Here is a little child, thirteen months old, with the following history. Three weeks ago the mother weaned it, and since then it has failed steadily. Its color is bad and it has lost its appetite. Its bowels move six or seven times a day, and what it passes is of a very light color. It has also some fever. The mother says that since she weaned the child she has fed it on everything that was on the table. Now it is important to know, first, whether this change in the child's health was a sudden change, coming immediately after weaning, or not. If it was gradual, there might be some other cause for the trouble. Before weaning, however, she says that she always fed the child on breast milk only, but since weaning she has given it potatoes, bread and milk, tea, coffee, and so forth. We might ask if she ever sees any of the food undigested in the passages. She says that she has seen pieces of meat. Food undigested passing along the alimentary canal in such a condition must act as a local irritant. A single piece alone, such as she describes, might give rise to a catarrh of the entire canal. The baby has eighteen teeth, so the mother says. That is a great many for a child of thirteen months to have. I will examine and see if that statement is correct. No, there are only fourteen. You generally have to make allowance for a mother's statement. Now this catarrh of the intestine deprives the child of nourishment in two ways. Whatever is introduced into the alimentary canal because of the exaggerated peristaltic action of the bowel is

immediately passed downward undigested. Besides, the mucous membrane of the intestine is changed in character, and loses its absorbent properties. So the food which the child takes is much of it passed unchanged. Such a diarrhœa is called lientery.

Now, as far as this case is concerned, the child has been nursed too long. It ought to have been weaned four months ago, instead of three weeks. Then, when the mother did wean it, the change from mother's milk was too sudden, and instead of giving the child what was similar to breast milk, the mother has allowed it to have pretty much the same food as she takes herself. Certainly this child has made a complete mistake in choosing a mother. If he had a different mother he would do much better. What is to be done for him now, to restore him to health? In this condition cow's milk alone is not easily digested. You must add an antacid, in order to prevent coagulation of the milk by the over-acid stomach. In such cases as these the milk, if given alone, is quickly coagulated into a large, tough curd. It is important then to add an antacid, and which one would you choose. There are several, such as the bicarbonate of sodium, the carbonate of magnesium and the carbonate of calcium. Which of them would you use in this case? Certainly neither the sodium nor the magnesium salts, because they are both purgative, and you have here a condition of excessive action and secretion in the intestine already. You would, therefore, make choice of the calcium salt. It is also important that the milk should be diluted, either with gum arabic water, half and half, or barley water in the same proportions or less. The milk may be boiled at once and farinaceous food may be given, the child being quite old enough. In a number of cases cow's milk is not digested, especially in bad cases in summer time. Then you must forbid milk at once and give barley water alone, or substitute the white of eggs for the milk. If this child had a little more diarrhœa than it has, I should forbid milk altogether. This treatment will have to be kept up for some time, ten days at least; for, lasting for three weeks, it is probable that the catarrh is universal, and it is also probable that the lymphatics of the abdomen are also congested and swollen, exactly as the glands in the neighborhood of the mouth become swollen when there is any trouble about the mouth or throat.

When the catarrhal trouble is of recent date only, it we have an opportunity of inspecting them, they look red and congested. When the inflammation has been more chronic, they are large, hypertrophied, and the seat often of caseous degeneration which may terminate in suppuration or induration, rendering them useless for purposes of absorption. That is one reason why I always insist on checking diarrhœa instantly, because of its influence on the abdominal glands. It is dangerous in so far as it renders useless the functions of these lymphatics. Now, we know that these glands do enlarge as the consequence of persistent diarrhœa, and therefore the prejudice which exists against stopping such diarrhœa immediately is not well founded, nor is there any reason for letting alone that diarrhœa which sometimes accompanies teething. It is only dangerous when let alone, and for the reasons stated. Now, as to this case, the cause of the intestinal catarrh is plain. There has been an improper choice of food. The food which has been given has not been digested, and has been passing along the mucous membrane of the alimentary canal all the time and acting as an irritant. This has been going on too long. The proper food I have already spoken of. As for medication, if there are at present any irritant substances in the intestine, a dose of castor oil, ʒj, which may be given in hot milk, will remove them. Further than that, what is to be done? What is the state of the mucous membrane? It is reddened, irritated, and bathed in catarrhal and serous secretion. The mucous follices are in a state of enlargement, and perhaps superficial erosion and ulceration. There must be, then, some local treatment, and there is no better remedy for this condition of things than bismuth. It acts both as a protection and a cover to the inflamed surface, and is at the same time also an anti-fermentative. It binds the sulphide of hydrogen. You may give of the subnitrate, or the subcarbonate, three to five grains, three times a day. No, it is better to give it oftener and in smaller doses, say two grains every three hours. There is here, besides, an undue amount of secretion and peristaltic action, so you may add a little opium, in doses of one thirtieth of a grain. Give one third of a grain of Dover's powder. For an antacid, do not give, as I have before said, either the sodium or magnesium salts, but in preference the carbonate of calcium, which is unirritating, and not a purgative. You may give it in doses of three grains. With such a treatment as this, and the addition of proper food, which is most important, this case will do well.

Medical Societies.

MEDICAL AND SURGICAL SOCIETY OF BALTIMORE.

Reported for the Med. and Surg. Reporter.

Sarcoma of Eyelid.

Dr. Chisholm. About one month ago a child, five years old, was brought to the hospital with a tumor of the lid which had been discovered only a few days before. The tumor was attached to the under surface of the lid by a pedicle containing large blood vessels; it was as large as a cherry and full of blood vessels; no pain was produced by its presence. For fear the hemorrhage might be dangerous a ligature was placed loosely around the mass, in preference to removing it by the knife. On the next day it had not lost its color, but was of a deeper red; some of the blood vessels had given way and the bandages were soaked with blood. Nothing more was done at that visit beyond giving iron for the anæmic condition. In a few days the tumor was of an ashy hue. Two days later it protruded between the lids. A ligature was applied which cut through the mass and it fell off. The eye was examined and found in a healthy condition, except a slight ashy appearance of the cornea, for which a lotion of boracic acid was used. Upon the child's return, two days

later, the cornea was entirely eaten away. It is singular that the slight pressure of the tumor should produce such destructive changes. The tumor was examined and found to be a sarcoma, containing both round and spindle cells, and nearly certain to return. It is three weeks since the mass was removed, and now it is nearly of the original size. The cornea has been replaced, but vision is lost, and probably life may be destroyed.

Abdominal Abscess.

Dr. Evans. Three or four months ago, I was called to see a lady, aged thirty, married, mother of children, one of which, nine months old, was still at the breast; always had good health up to the present illness. After her confinements the menses usually appeared within six months, but at the time I saw her they had not been present since the birth of her last child. She was taken with a chill and severe abdominal pain, and a medical gentleman who attended her for eight weeks pronounced the case one of Bright's disease, and would be fatal. When I saw her there was great dyspnœa, anasarca, and almost complete suppression of urine, half a teacupful of coffee-colored urine being passed in the twenty-four hours. I feared to give her diuretics, but gave one drop of croton oil every two hours, until free watery evacuations were produced. In the evening she passed a larger quantity of water, and was much relieved. The next day I repeated the oil, with manifest benefit. Then ʒj fld. ext. jaborandi was given, which produced free diuresis. The kidneys had recovered from their engorged condition and the urine flowed freely; then potass. bitart was used to keep up the flow. All this time there was no pain, and the improvement continued for ten days, when the dropsy reappeared and the croton oil was repeated for two days. She then complained of pain, and the fluid extract of juniper was used as a diuretic. On the next morning she had a hemorrhage from the bowels and passed a large quantity of pus. The flow of pus continued for several days, and gradually lessened in quantity. I think she passed several gallons. She made a good recovery, and is now well. I do not think she had Bright's disease. If this was an abscess dependent upon parturition, it is singular that she was perfectly well for nine months after delivery. It would be very strange for an abscess to exist that length of time and show no signs of its presence.

Abscess of Tonsil.

Dr. J. H. Hartman. A young adult had severe pain on deglutition and a burning in his throat. His father thought he had quinsy, and under the use of gargles and domestic remedies he seemed to be doing fairly until a day or two before he came to me. The left tonsil was swollen as large as a pigeon's egg, and there appeared to be deep-seated inflammation. The swelling was opened freely and much pus escaped. Further inspection revealed a white substance in the tonsil, which, upon extraction, proved to be a piece of wooden toothpick, about half an inch long. This is the first case of the kind that has come under my observation, although many cases are reported in the books. Fish bones, tooth-brush bristles, apple-seeds, etc., have been found in the tonsils, and have produced abscess. I have frequently, in excising the tonsil, met calcareous concretions, sometimes as large as a bean. More than once I have been compelled to remove the tonsilotome and finish the operation with a bistoury.

Gunshot Wound.

Dr. Cathell. A man was shot in the mouth on last Thursday. The mouth was open at the time and the ball struck the palate about half an inch to the left of the median line, was deflected by some cause and made its exit under the mastoid process of the right side. There was only slight hemorrhage, not much pain, and no paralysis. There is extreme stiffness of the neck, but nothing of serious import up to the present. It is too soon to say what complications may retard the recovery, such as abscesses, secondary hemorrhage, pyæmia, or even tetanus.

Some years since I saw a case which was very peculiar. A man was shot just above the knee; the efforts to find the ball failed, and profuse suppuration, with emaciation and hectic, followed. Necrosis was thought to exist, and the man got a pension on account of the wound. A surgeon, in examining the case, some years after, found a prominence near the seventh cervical vertebra, upon which he cut, and removed a large bullet. The wound was received during the war and the removal of the bullet was in 1868. The suppuration ceased and the man made a complete recovery in a very short time, and has had no trouble from this source since. How the ball could travel from the knee to the back of the neck is difficult to tell.

Periscope.

Phimosis as a Cause of Hernia in Infants.

Some valuable remarks on this subject were made at a society meeting in Kent, England, by Mr. S. Osborn, F.R.C.S.E.:—

Having, in my capacity as surgeon to the Surgical Appliance Society, to examine and apply some hundreds of trusses in the course of a year, the frequency of phimosis in combination with rupture in infants has struck me repeatedly, more especially just lately, as I have had no less than ten cases within the last month. The phimosis in all these cases, I am certain, was the undoubted cause of the rupture, and may be thus explained. After the descent of the testicle into the scrotum has been accomplished, the vaginal process of peritoneum through which it descended begins to close and become converted

into a fibro-cellular cord. But the testicles having but lately descended (the left coming down between the seventh and eighth month of fœtal life, and the right between the eighth and ninth month), the uniting medium is yet but young, and not being sufficiently organized, is easily broken down by any strain thrown upon it. Phimosis occasions that strain, from the impediment which it offers to the outflow of urine. For the mechanism of ordinary micturition is effected by the contraction of the muscular coats of the bladder and urethra; but in cases of obstruction to the outflow of the urine, extraordinary force is called into action, and this is effected by the contraction of the abdominal walls pressing upon the bladder, while the diaphragm is also at the same time in a state of tension. By this means pressure is exerted over the whole of the abdominal wall, and the apertures by which the testicles have descended to the scrotum being always the weakest points of the abdominal surface, they naturally give way under the strain thrown upon them. In other words, the child, straining to pass his water, forces the abdominal contents downward upon the weak points at the inguinal canals, and rupture on one or both sides results. I would go even still further than this, and say that the canal which has been the last to close, or, in other words, that side on which the testicle was the last to descend, is the side on which we usually have the rupture occuring; and knowing that the right testicle is generally the last to descend, we naturally find that hernia in infants is also encountered with greater frequency on this side. That the rupture occurs on the side on which the testicle was the last to descend is only what one would suppose, for the uniting medium which is effecting a closure of the canal on this side is not in so advanced a condition of organization as on the other side, where the testicle has taken its place prior to the other. It is thus easily seen how a single truss frequently produces a double rupture. The cause of the obstruction to the outflow of urine is still present in the phimosis, and one inguinal canal being guarded by the single truss, the abdomen gives way at its next weakest point, viz., the other inguinal canal, and a double rupture is the consequence. Such a result might have been prevented by early circumcision. The hernia in these cases is generally scrotal, or, if not, it soon becomes so by the wedge-like projection of the intestine; and as to whether it be congenital or infantile in variety, depends upon the amount of the funicular process of peritoneum which has become converted into fibro cellular tissue, or which has been broken down by the aforesaid propulsion of intestine. The operation of circumcision, as performed upon young children, and which was done in all of the cases I previously spoke of, is both easy of performance and effective in its results: easy of performance because no sutures are ever required (children bear pain well, and the parts are usually well in a week or ten days); effective in its results, because the hernia then stands every chance of being effectually cured by the application of a truss, the exciting cause having been removed, and, at all events, a double rupture is prevented by its early adoption. Occasionally difficulty arises in the operation when the rupture is very large; for the penis, buried by the projection of the rupture, is represented in such cases by a button-hole aperture, and the operation is then more easily effected by the rupture being commanded by a double inguinal truss during the performance of the operation. In conclusion, I would suggest, then, that whenever an elongated or contracted prepuce be present in infants, the sooner circumcision is performed, the better; thereby the more serious complaint of rupture will be prevented.

Treatment of Pain by Mechanical Vibrations.

For some years past, says the *Lancet*, Dr. Mortimer Granville has been occupied with important researches upon the possibility of combating neuralgia by mechanical means. Proceeding largely upon theoretical considerations, he came to the conclusion that a series of interrupted mechanical shocks to a nerve would diminish its sensibility, and for that purpose invented a small instrument whereby a succession of rapid blows could be kept up upon the skin. Many physicians in London and Paris have seen and employed the apparatus, and spoken of it with approval; but Dr. Granville forbore to bring it under general notice until it had been thoroughly tested. He has paid the penalty of his patience, and the old story is repeated of the publication of an idea by another person, by whom it was conceived long after the one who first thought of it, but who did not proclaim it to the world. In justice to himself Dr. Granville should forthwith point out how he arrived at the idea, and state his experience of its practical enforcement. Meanwhile it may be interesting to summarize the statements of M. Boudet de Paris, who writes on the subject in *Le Progrès Médical*. After alluding to Dr. Brown-Séquard's observation, that chloroform applied over the skin of an animal produces general anæsthesia by its irritant action on the peripheral nerves, he points out that all irritants or revulsives may be placed in one category—such as actual cautery, hypodermic injections of water, application of metals, magnets, tuning-forks, electricity, vesicatories, sinapisms, compresses steeped in ether or chloroform, a motley group, but each intended for the same end—the relief of pain; they all operate by irritating the terminal twigs of sensory nerves. Vulpian long ago showed the good effect of the local application of chloroform; and Landouzy has recently pointed out the remarkable influence, in controlling the cough of phthisis, of hypodermic injections of water; while the cautery, acupuncture, and each of the forms of electricity are commonly applied to relieve pain. The action of metallic applications—metallo-therapy—of which we have heard so much in the last few years, was best explained on the theory of vibrations, by Vigouroux, who proceeded to experiment upon the effect of sonorous vibrations, which he thought might have a direct mechanical effect upon the sensory nerves. By the aid of a large tuning-fork and sounding-board he caused hemianæsthesia to disappear, and evoked contractions in hysterical subjects at Salpétrière, as rapidly as with the magnet or electricity. The pains of an ataxic were sub

dued when his legs were brought under the influence of these sound-waves. M Boudet de Paris then thought this might be applied locally over a nerve—the sonorous being changed to mechanical vibrations by means of a small button attached to the resonater, and applied over the nerve. He therefore contrived a small apparatus consisting of an electrically mounted tuning-fork, the vibrations of which were transmitted to a rod which could be easily applied over a nerve. In a healthy man this mechanical excitation pro duced rapid local analgesia, often anæsthesia, the maximum effect being produced by application over a nerve which could be compressed on a bony surface. When placed against the skull its walls vibrate in harmony with the tuning-fork, and a sensation of approaching vertigo, frequently followed by a desire for sleep, is produced. An attack of migraine can be cut short by the application. Neuralgia—especially of the fifth, where the nerves issue from bony canals—disappears after a few minutes' application of the instrument to the nerve at such points, but in the case of deeper seated nerves, much protected by soft parts, it is more difficult to get good results. The writer suggests this treatment for the pains of ataxics and syphilitics; he thinks there is no limit to its applications, and suggests that perhaps cranial vibrations may induce cerebral, and thus general, anæsthesia. Its mechanical action is comprehensible, when we see how simple friction of the skin may soothe very acute pain. He does not regard the number of vibrations as important. This, however, is, we believe, a point on which Dr. Mortimer Granville lays the greatest stress.

The Tribasic Phosphate of Silver in Organic Nervous Disease

This substance, prepared by Caswell, Hazard & Co., of New York, is thus mentioned in the *Lancet*, Feb. 19th, by Dr. A. McLane Hamilton:—

The tribasic phosphate of silver possesses advantages over the other silver salts which entitle it to a fair trial. I have given it for months, in doses varying from one-third to half a grain, without any skin discoloration whatever, and its administration is unattended by the gastric irritability that so often follows the use of either the nitrate of silver or the phosphide of zinc. At the same time its therapeutic effects are much more pronounced. It is best given with some such excipients as argol and glycerine, for vegetable substances tend to decomposition; and for this reason I have discarded the confection of roses as an element of the pill mass.

In the first edition of my work upon Nervous Diseases I directed attention to the probable advantages of this drug, especially in sclerosis of the posterior columns. The experience of two years has convinced me that it is my duty to urge others to make use of the remedy. In two classes of cases it has proved to be of great value: 1. In those of more or less acute myelitis with disturbance of the bladder and rectum. Not only in such cases of transverse disease has there been a decided improvement in the matter of control over the functions of these organs, but there has been a decided gain in the muscular power. This has been conspicuous in a very remarkable case of chronic meningo-myelitis seen in consultation with Dr. Todd, of Ridgefield, Conn. 2. In cases of sclerosis of the nervous substance. In seven cases of posterior spinal sclerosis there has been a subsidence, more or less, in the violence of pains, and in those who have taken the drug for over a year the power of locomotion is materially increased.

In six cases of inveterate epilepsy, as the result of gross inflammatory intracranial changes, the patients have been relieved, judging from the diminution in the number of the attacks.

I am now giving the drug to patients with cerebral tumor and general paralysis, and while it would be out of the question to expect anything like permanent cure in such hopeless diseases, I do believe that a persistent and proper use of the silver salt will do much more for the patients than any of the drugs hitherto used. I can find in medical literature no record of the use of the phosphate of silver, nor am I able to learn by inquiry that it was used prior to 1878. I sincerely hope that others may be prompted to publish their experience.

Diagnosis of Adherent Placenta.

Dr. A. C. Air writes to the *Lancet*, February 5th:—

I have met with several cases of morbidly adherent placenta, during the last fourteen years, and am inclined to believe that the diagnostic problem may be solved with almost absolute certainty; although, from my experience being limited to so short a time, I would desire to write with all becoming modesty.

The diagnosis is, I think, to be founded upon two symptoms, one of which is mentioned by Dr. Churchill, the other by Dr. Barnes, viz., that at some period of pregnancy, generally between the third and fifth month, a fixed pain, generally of a dull, aching character, is felt over some part of the uterus; and this is converted into a severe *dragging* pain when the patient attempts to turn over to lie on the side opposite to the placenta site; so much so that patients with an adherent placenta will never (as far as my experience goes) voluntarily lie on that side. This pain, I believe, to be of the same nature as that mentioned by Dr. Barnes as being experienced when the cord is drawn upon; and is due to the dragging on the cord by the child, when, from gravitation, it sinks through the liquor amnii.

Theoretically, it may be objected to this explanation that usually the cord is sufficiently long to prevent any such dragging; but I think it will generally be found that when the cord is long it is twisted around the neck or limbs of the child, and produces the same effect as a short cord would.

No history of this dragging pain on the patient's turning to the side opposite to the placental insertion will be obtained when the retention of the after-birth is merely due either to the inertia of a wearied uterus, or from irregular contraction; if there is hemorrhage in either of these cases, one would be justified in trying the

effect of cold, compression, etc., before introducing the hand, but in cases of true placental adhesion, trying these and similar means leads to dangerous loss of precious time.

Two Yards of Intestine Removed.

A Paris letter in an English contemporary describes a remarkable case in the practice of Dr. Kœberle, of Strasburg.

The patient, a young woman, aged twenty-two, had been subject for some years to acute attacks of abdominal pain, and on two occasions there had been symptoms of obstruction, which had, however, been overcome by the use of enemata. Since that time (October, 1880) the pain had been most constant and severe, not remitting day or night, and at times so intense that it could scarcely be soothed by hypodermic injections of morphia. Gastrotomy was performed on November 27th, 1880, and four narrowings were found in the bowels, one being only four millimeters in width. These strictures were distributed over two yards of the gut (2 meters .05), which was excised between two ligatures at each extremity, the vessels of the mesentery being secured by twelve ligatures. The ligatures of the ends of the intestine were then tied together so as to place the gut in the most favorable position for enterotomy, which was performed on the third day. The parts beyond the ligatures came away between the twelfth and fifteenth days, and on the twentieth the first alvine evacuation occurred. Five days later a band of strapping sufficed to prevent food or gas passing through the wound, which had entirely healed in six weeks. The operation was not performed antiseptically, and the temperature never rose beyond 38° Centigrade. During convalescence, and from the third day, the patient was fed by the mouth, with solid and substantial food—bread, meat and eggs—sufficient liquid being given for the purpose of digestion only, the thirst being assuaged by injections of water in the rectum, seventy such injections having been made in the twenty days. The young woman, who is now quite well, has no pain or digestive trouble of any kind.

Complete Extirpation of the Uterus, With Both Ovaries.

Dr. Thomas Chambers reported this case to the London Obstetric Society:—

Jane S., aged 45, was admitted into the Chelsea Hospital for Women, May 24th, 1880. In 1870 she first noticed a lump in her right groin, which grew slowly for five years. After this menorrhagia commenced, and gradually increased. Pain and hemorrhage were excessive, and she eventually became too weak to attend as an outpatient, and was remarkably emaciated. The tumor was freely movable from side to side, and was very soft and doughy, but without fluctuation. The pelvic cavity was unoccupied, the vagina drawn up into a cone, with the os and cervix, both small, in the centre. There was a periodical discharge of watery fluid through the vagina. Hence a diagnosis of fibro-cystic tumor was made. Medical treatment having proved of no avail, extirpation of the uterus was proposed to the patient, and she decided in favor of the operation. It was performed on June 22d. The abdominal incision was extended to eleven inches. The broad ligaments were tied with silk at each side, a parallel clamp placed above the ligatures and the uterus cut away. After a few minutes arterial hemorrhage occurred from a large vessel, which was at once secured. The cervix was then transfixed by a double ligature, the clamp removed, the ligatures tightened, and the stump replaced. By the 21st day the patient was convalescent, a free discharge of offensive matter from the vagina having taken place suddenly on the 14th day. The tumor proved to be a lobulated white fibroid, not fibro-cystic, and contained very large vessels.

The Temperature in Tubercular Meningitis.

Dr. Jules Turin, in an interesting article on Tubercular Meningitis, in the *Jahrbuch für Kinderheilkunde*, vol. xvi, quoted in the London *Med. Times and Gazette*, sums up the question of temperature as follows: 1. Tubercular meningitis is always accompanied by a rise in temperature in one or other of its stages, but very seldom during its entire duration. (The stages are given according to Dr. Whytt, who, as is well known, first described the disease). 2. In a few cases only does the disease begin with a sudden rise of the bodily heat, as in some forms of acute disease. 3. The thermometric results are extraordinarily variable, so that it is quite impossible to establish any typical temperature curve. 4. In uncomplicated cases of tubercular meningitis the temperature rarely exceeds 102.2° F.; it generally varies between 100° F. and 102° F., but it may also sink some degrees below the normal. 5. The most common type is the remittent, with the usual day fluctuations. The variations within twenty-four hours are normal, or more than normal; sometimes they are very irregular, with more or less sudden rise or fall at any stage and at different periods in the twenty four hours. 6. If the tubercular meningitis is the terminal affection of some previously existing febrile disease—as, for instance, a coxitis, or any bone or joint lesion—the average temperature will be higher than in other cases; but, in other respects, the course of the disease will be unaffected. 7. In the cases with acute general miliary tuberculosis the febrile exacerbations are more considerable and the variations more marked.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Part III. of Dr. Isaac Ott's "Contributions to the Physiology and Pathology of the nervous system" contains reprints of various articles contributed by him to different periodicals during the last year. The subjects of some of these are "Crossed Hyperæsthesia," "Notes on Inhibition," "Bromide of Ethyl," "Urechitis Sub-

erecta," etc. Dr. Ott is a careful and intelligent worker, and his studies are well directed and valuable. Published by the author, at Easton, Pa.

——A neatly gotten up little book by Dr. Joseph F. Edwards is "Constipation plainly treated, and without the use of Drugs." (Philadelphia: Presley Blakiston, 12mo., pp. 72, cloth. Price 75 cents). He has chapters on the functions of the stomach and bowels, on the necessity for daily evacuations, and on how to procure daily evacuations without the use of drugs. He recommends fruits, appropriate exercise, laxative diet, fluids, massage, etc. It is apparently written for the public rather than for the profession.

——In a neat reprint Dr. John Homans, of Boston, reports the details of 25 consecutive cases of ovariotomy. He had the remarkably good results of twenty two recoveries and only two deaths (one under treatment). We recall no statistics more cheering than these. Nor were they "picked cases;" on the contrary, he distinctly claims that the operation is justifiable in the face of great odds. He says:—

I think there is a normal duty involved in undertaking to practice ovariotomy, namely, that a surgeon is bound at times to operate in cases where he can give but little hope for a favorable result. This becomes more and more a duty as time goes on and the operation becomes more and more firmly established. In the earlier efforts to make the operation one to be advised and urged, it would have been wise to select for operation only those cases almost certain to recover, in order that ovariotomy might not fall into disrepute; but now I think an ovariotomist ought to be willing to operate in a case like Number XXXIV, for instance, where the contents of the tumor were so thick that they could only be removed through an incision which would admit the hand. Here there was a possibility of recovery and a certainty of a speedy and distressing death.

Antiseptic precautions seem to have been used pretty generally.

BOOK NOTICES.

Lectures upon the Diseases of the Rectum and the Lower Bowel. By W. H. Van Buren, M.D., LL.D., etc. New York. D. Appleton & Co., 1881. 8vo., pp. 412. Cloth. Price $3.00.

This is an enlarged and improved edition of the author's lectures, as published some years ago. Diseases of the rectum are so frequent and entail such an amount of annoyance and actual misery, that a standard work like the one before us, on this subject, is next to indispensable to a physician's library. How common are piles, fistulas, fissures, ulcers, and diseases of the rectum! Pruritus ani is another abominable annoyance to thousands, and its causes are very various. Dr. Van Buren's treatment of seat worms we have often had occasion to put into practice, and with rare failures. The chapter on cancer of the rectum is very complete. Extirpation of the rectum is spoken of with qualified approval, as at least affording a respite from the disease. The operation itself is apparently not particularly serious. All of the nine cases for which the author "was responsible," as he phrases it, recovered from the procedure, and two of them continued in good health two years afterwards.

The volume is printed in large type, on fine paper, and has twenty-seven illustrations.

Imperfect Hearing and the Hygiene of the Ear Including Nervous Symptoms, Tinnitus Aurium, Aural Vertigo, Diseases of the Naso-Pharyngeal Membrane, Middle Ear, and Mastoid Region. With Home Instruction of the Deaf. By Laurence Turnbull, PH. G., etc. Third edition. With illustrations. Philadelphia: J. B. Lippincott & Co. 8vo. Cloth. pp. 147. Price $2.50.

Dr. Turnbull is extensively known as an aural surgeon of eminence, and his works have always been received with much satisfaction by the profession. In the one now before us he takes up a number of topics connected with diseases of the ear and adjacent parts, and discusses them both in the light of his own extended observation and also with reference to the recent literature of this specialty. Dr. Turnbull acted as president to the sub-section of Otology at the British Medical Association, in 1879, and chairman of the corresponding section of the meeting of the American Medical Association last summer, posts which gave him unusual facilities for learning and comparing the views of the most distinguished otologists of both hemispheres.

The topics he dwells upon are pretty fully set forth in the title above given; others are, "The limit of perception of musical tones by the human ear," "artificial perforation of the membrana tympani," "the prevention of deafness," and "a comparison between the audiphone, dentaphone, etc., and the various forms of ear trumtets." These various subjects are treated clearly and free from partisanship. The book is well illustrated and neatly manufactured.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE DISEASES OF ANIMALS USED FOR FOOD.

On various occasions within the last few years we have spoken urgently of the importance of giving greater attention to veterinary medicine, and of studying diligently the diseases of the lower animals. Recent occurrences have impressed on the public mind how essential that is to the welfare of our nation. The doubtful or bad reputation which American pork, etc., has gained abroad, through the frequency of trichinous disease in it, or of the prevalence of hog cholera, has led to severe pecuniary losses in the United States, and at last to a prohibition of the introduction of this staple food into foreign nations. The reasons they give are simply that in so many instances animal food shipped from the United States has proved, on inspection, to be the flesh of diseased animals, and capable, when used as an article of consumption, of producing disease in the human race.

Unpleasant enough is the conviction forced upon the American mind that the authorities of the European States, however anxious to receive cheap food, do not intend poisoning their subjects for our benefit. It is well enough for our officials to make quite a noise about an arbitrary distinction drawn against American products; but it would be a great deal better if they would expend their energies in establishing Boards of Health, Inspectors of Food, Examiners of Stock Yards and Slaughter Houses, and in other ways providing for the protection of our own and other people against contamination by diseased meat and fraudulent foods.

We shall heartily thank the French and Germans, if, by their action, they force upon our government the necessity of such supervision, inasmuch as thereby they will protect our own people. Thousands of people, no doubt, die every year in the United States, of trichinosis, whose real disease is entirely unrecognized by their physicians. From the French reports, it would appear that a large proportion of American pork contains trichinæ, and as forty million pounds of this meat are said to be imported annually from America to France, it became neces-

sary to take steps to protect the public from the danger which menaced them. An official instruction was circulated in January, calling the attention of food inspectors to the question, and a large quantity of meat was, in consequence, seized, and found to be diseased. At the Academy of Medicine of Paris, a sitting was also devoted to the subject, and various schemes for protecting the public were proposed by different speakers. The matter was settled by a decision, made by the Minister of Commerce, on the recommendation of the Council of Hygiene, which forbids any further introduction of American salt pork into France.

No one but a pork merchant with a very elastic conscience could have anything to say against their action. It was perfectly proper, and we justly merit the discrimination against us, by reason of our constant negligence in reference to diseases of the lower animals and their prevention. What an honest care for the welfare of our own people has never led government to do, perhaps now the lowest motives of self interest will succeed in accomplishing.

This matter of trichinosis is a serious one. It is far from true that simple cooking is a perfect safeguard. This has been lately almost demonstrated by M. Vacher, of Paris, whose authority is of considerable weight. He affirms that the protection given by cooking is quite illusory, and that in the thorough cooking of an ordinary joint of meat the temperature in the centre is not sufficient to insure the destruction of the parasite. He took a leg of pork of moderate size and boiled it thoroughly. A thermometer placed within it at a depth of two inches and a half, registered after half an hour's boiling 86° F., after boiling for an hour 118°, after an hour and a half 149°, and after two hours and a half, when the joint was thoroughly cooked, 165°. This temperature M. Vacher maintains is insufficient, and we must remember that at the centre, which is still further from the surface than the bulb of the thermometer was placed, the temperature would not be so high. "Trichinæ would escape almost entirely the action of boiling water" in cooking. M. Vacher's note was communicated to the Chamber of Deputies, and no doubt has influenced the decision of the French Government to prohibit entirely the importation of American pork.

Very different from this is the cheerful statement of Dr. John H. Rauch, Secretary of the Illinois State Board of Health, which was published in the daily papers, March 15th. It runs as follows:—

"Since 1866, eleven deaths have occurred in Illinois by trichinosis, and in every instance from eating raw ham or sausage. As a sanitarian, I regard the danger to life from this source as practically amounting to nothing, it being so easily prevented by cooking. No doubt more deaths occur from many other articles of diet that are regarded as harmless, no record being made of the same. Of the millions of hogs that have entered Chicago in the past two years, only two hogs have died of trichinosis."

Now, in making this statement Dr. Rauch was either quite ignorant of what he was writing about, or he made it in the interest of the pork packers, with a very slight regard to scientific accuracy. If he had studied the subject at all, he must have known that the multiform aspects of trichinosis puzzle even experts (See the Reporter, November 20th, 1880, Editorial), and that any such assertion as the above is baseless. Generally, death from trichinosis is set down to typhoid fever. Moreover, the fact (if fact) that only two out of millions of hogs have died of trichinosis in Chicago, is not to the point. Was the cause of the death of every hog ascertained? If so, then the hogs have much closer sanitary inspection than have the people of Chicago. But the relative malignity of the disease in man and hogs differs greatly; the parasite is far more injurious to the human species.

We regret to see Dr. Rauch thus overlooking the sanitary welfare of the people of Illinois, for the interests of a few of its meat merchants.

The hog cholera is another terrible scourge. In 1878, 14 per cent. of the entire "hog crop" perished in Illinois; the year previous considerably over a million animals perished; the average annual loss for the last ten years, in that State alone, is above half a million swine.

There are many other diseases of animals used

for food which impair the healthfulness of their flesh. Many of these maladies destroy millions of dollars worth of live stock every year. There is every reason to believe that they are preventable, at least, in great measure. What is wanted is the assistance of the government in their thorough investigation in the first place; and next to that, a general popular instruction of the agricultural classes in the hygiene of animals, and the simpler methods of treatment and recognition of diseases.

For years we have been urging the better education of agriculturists in this matter; and now the Committee of the Board of Trade of Chicago come out and say that these great losses and disturbances of trade arise primarily from "the lamentable ignorance among farmers, about the hygiene and diseases of their animals." Let us have no deception about this matter, and no misunderstanding as to what should be done. The root of the evil is here plainly shown.

WOMEN AS PHYSICIANS.

There is nothing like the logic of facts. To it all theories must be brought and tested. It is vain to attempt to escape its verdict.

The question whether women are calculated to be successful in the profession has been debated vigorously. Now is the time when we can ask, *Have they been* successful? The record is before us and open for inspection.

The Valedictory Address of Dr. Rachel L. Bodley, Dean of the Woman's Medical College of Philadelphia, placed this matter before her hearers. Her theme was a statement of the work accomplished by their Alma Mater in the thirty years of the existence of the College, as exemplified in the professional careers of her 276 daughters sent out as medical graduates during that time. To enable herself to speak with precision Dr. Bodley sent to each of the 244 surviving graduates (32 had died in the thirty years) a circular containing eight questions, to which she solicited answers. The questions were designed to cover the prominent features in the experience of the medical women graduated by the College, in the practice of their life work—its professional character; its pecuniary rewards; its social status; its teaching work; its membership in medical societies, and finally, that important question in sociology touching the influence of the study and practice of medicine upon woman's relation as wife and mother. Of the 244 surviving graduates, answers were received from 181, and of this number 151 are in active practice as doctors, the remaining 30 having given up, for various reasons, among which are domestic duties, philanthropic work, other business, poor health, retired, old age; and in some instances no reason was assigned.

We shall give the words of the lecturer on some of the other points:—

The second question related to the predominating character of the medical practice of the 151 who are thus actively engaged, whether gynæcological, obstetrical, surgical or medical. The responses are as follows:

Gynæcological practice predominating, 32; obstetrical, 9; medical, 9; surgical, 3; general practice, without discrimination, 34; gynæcological and obstetrical, 19; gynæcological and surgical, 6; gynæcological and medical, 26; obstetrical and medical 6; surgical and medical, 7. Total 151.

The third question relates to the social status of the woman physician in the community in which she dwells.

One hundred and fifty-one answer this question, and of these 144 report cordial social recognition. These answers are often emphasized and frequently accompanied by testimonials in proof thereof. Seven report negatively. These seven dwell in communities which may not be named here, since the announcement would be accompanied by possible annoyance to the ladies interested. These exceptions recall the character of public opinion twenty-five years ago, in many communities which are now happily advanced and reformed to the extent of permitting every woman to cultivate her talents and to engage heartily in whatever good work her hands may find to do.

The fourth question interrogates in reference to the work accomplished by the woman practitioner, as resident or visiting physician in hospital, asylum, charitable institution, or as physician in college or school for girls. To this question 157 make reply: 59 are thus engaged. The record in this regard is inspiriting. In our own State of Pennsylvania, one is physician in charge of Woman's Hospital of Philadelphia; one is resident physician to department for women in State Hospital for the Insane of the Southeastern District of Pennsylvania; one is assistant physician of State Hospital for the Insane, Southeastern District of Pennsylvania; one is assistant physician Pennsylvania State Lunatic Asylum, at Harrisburg.

In New York, one is resident physician of Nursery and Children's Hospital, Staten Island; one is assistant resident physician, same institution; one is resident physician House of Mercy for Girls (a charitable institution); eight are assistant physicians in the Woman's Hospital of Philadelphia, and in the New England Hospital in Boston; besides these are consulting and visiting physicians to hospitals and charitable institutions, members of consulting boards; one alumna occupies the responsible position of physician to the State Industrial School, Lancaster, Mass.; others have in the past occupied similar positions, as the position of resident in our own Woman's Hospital, resident of the N. E. Hospital for Women and Children in Boston, the late Mission Hospital of Philadelphia, etc., etc. Besides this service in hospitals, several record themselves as resident or visiting physicians to schools for girls; one as an auxiliary visitor to the State Board of Charities in Massachusetts, etc., etc. One states that she was City Physician for one year to the city of Springfield, Mass. Another is now Health Officer to the city of Charlotte, Michigan. The frequent mention in the answers to this fourth question, of being physicians (usually without salary) to "Home for Erring Women," "Orphans' Home," "Home for Girls," "Reformatory School for Girls," "Infirmary for Infants," "Children's Home," "Home for Aged and Infirm Persons," etc. etc., suggests the wide and fruitful field opened by medical work to true-hearted women, skillful and wise physicians, wherein they may accomplish great and lasting good for their race.

The fifth question relates to the monetary value of the medical practice per year, and is answered by 76 ladies.

24 as much as $1000, and less than $2000.
20 as much as $2000, and less than $3000.
10 as much as $3000, and less than $4000.
5 as much as $4000, and less than $5000.
3 as much as $5000, and less than $15,000.

Four report sums varying from $15,000 to $20,000 per year. Ten report less than $1000 per year.

The average income is found to be $2907.30 to each of 76.

The four who report the exceptional large sums are established practitioners, and have reported the amount each year for several years.

These sums may, probably, be relied upon by the social statistician as fair averages of the income of women physicians, since many are careful to state that they give only actual receipts, as indicated by bank-book or ledger, and several decline to attempt to reply, stating as the reason that they are too busy to make an accurate estimate, and they are unwilling to hazard a guess. Several, who make no estimate, reply that they are able to support comfortably families varying in size (frequently stating the number in family), father, mother, and brothers, mother and sisters, several nephews and nieces, etc., etc. Three women doctors report having accumulated sums sufficient to permit them to retire from active service.

Question sixth referred to the work for which woman is pre-eminently fitted, that of medical teacher, and specified separately institutions of learning and popular audiences of women. Fifty-four answer this question affirmatively. Among these are seven professors in medical colleges in Philadelphia and New York, and twice that number of lecturers and instructors in our own college and in the medical college for women in Chicago. The statements which have come in relative to the popular course of lectures on medical subjects, for women, are highly gratifying. Sometimes the audiences have been large ones, in cities; sometimes they have been "talks in my office," with my patients; sometimes "instruction of my office students;" and often "lectures on physiology and hygiene" in girls' schools; and oftener still, as private letters which have accompanied answers have stated, the teaching has been of the character set forth in the letter of an alumna who is practicing far out on the Western prairies, when she writes: "I am daily thankful for the privilege of teaching women (in their homes) how to take care of themselves and how to preserve the health of their children."

The seventh question is the inquiry which, in later years, has assumed (with us) especial interest, in deciding the professional status of women physicians, viz., that of membership in medical societies. Sixty-six reply affirmatively to this question. "Are you a member of a county, State, or other local medical society?" Of these, four reside in California, one in Connecticut, one in Delaware, four in Illinois, one in Indiana, three in Kansas, two in Massachusetts, five in Michigan, two in Minnesota, one in Missouri, one in New Hampshire, fifteen in New York, six in Ohio, fourteen in Pennsylvania, three in Rhode Island, one in Tennessee, one in Wisconsin—seventeen States in all.

The professional ability of many of these ladies has been recognized by election to membership in more than one State or local medical organization. Thus, the accomplished author of the Boylston prize essay for the year 1876 reports membership in six societies, five in New York city, and in the American Medical Association. Another alumna, practicing in the largest city in Ohio, reports membership in four societies, three prominent local organizations, and the American Medical Association. Then, again, especial distinction has been conferred upon others by enjoyment of sole membership as women practitioners of medicine, as in the Boston Gynæcological Society, where membership has been accorded to but two women, and both of these are alumnæ of our college. Seventy-three different medical societies in all, throughout the United States, have thus honored women. Five of our graduates have represented their respective State societies in the American Medical Association, viz.: Delegates from Rhode Island, Ohio, Illinois, New York and Tennessee. But eight women have as yet enjoyed this honor of representation in the American Medical Association. The preponderance is, therefore, in favor of our college—five out of eight. An alumna, practicing for some years in Minnesota, writes that she holds the appointment of delegate to the American Medical Association for 1881. Montgomery County and Delaware County (Pa.)

Medical Societies, have each elected a college alumna as a delegate to the Pennsylvania Medical Society which will meet in Lancaster in May, 1881.

While to Pennsylvanians it may be gratifying to note the number (14) admitted to membership throughout the State, the membership in regular Medical Societies in the county of Philadelphia is far from satisfactory, if we had the time to enumerate localities who have granted membership to women. The papers have come in from all our Philadelphia Alumnæ (30 in number) with the brief answer, "No." One Alumna writes from Iowa, that on the 3d of February, 1881, she was invited to accept the position of member of the Medical Examining Committee of the medical department of the Iowa State University.

To the last question (the eighth) 61 make answer. The inquiry is worded thus: "What influence has the study and practice of medicine had upon your domestic relations as wife and mother?" As it is concerning the phase of influence suggested by this question that our critics make their severest comments, so it is the most difficult to present truthfully the impression made by the answers received. I have decided to let the statistics speak for themselves.

The answers of the 50 married ladies who respond to this question tabulate as follows: Influence, favorable, 43; not entirely favorable, 6; unfavorable, 1.

Unmarried ladies' reply to this question after striking out from the line, the words "wife and mother." Three state that the study and practice of medicine have prevented marriage, while a fourth states definitely that she has "remained single for reasons entirely distinct from her profession."

Returning to the answers of married women, because these possess the greater general interest, I remark that the song of domestic life, as I have listened with ear attent, has been sung in no minor key. In the melody (as the tabulated statement shows) are a few discordant notes, but these are such that a master might throw in to enhance the harmonies of his strain. For example, a thoroughly conscientious mother writes from her nursery, where three quite young children claim the mother's ministry: "The *study* of medicine is of great benefit, but the practice often interferes with the duties to my family." The clear, pure quality of the replies, as a whole, is truly inspiriting; for example: "Purifying and ennobling. Married a physician since I began practice. Am the mother of a boy of eight years of age." Another: "As wife my duties have never been interfered with; as a mother I have been incalculably benefited. * * * My husband is also a physician. I am often enabled to assist him with his cases, both in diagnosis and treatment, and I often find his advice of great value to me. We are, mutually, a help to each other."

The general impression which these statements convey cannot be misconstrued. Even allowing for the natural bias of the lecturer in favor of the cause she advocates, there can be no doubt but that the results she states will compare very favorably with those from a similar number of male graduates. As far as it goes, it is a strong vindication of the propriety of those women studying medicine who have tastes and talents in that direction.

Notes and Comments.

Means of Checking Phthisical Cough.

In the *Progrès Médical*, November, 1880:—

Dr. Landouzy, after describing the suffering which the subjects of phthisis undergo from the paroxysmal cough to which on the slightest occasions they are liable, and the mischievousness and inutility of the means usually tried, without avail, to arrest these, states that a considerable experience enables him to rely upon an easy, rapid, and inoffensive procedure for arresting this distressing occurrence. It consists merely of a subcutaneous injection of a syringeful of distilled water, to which a few drops of cherry-laurel water have been added. The injection is made in the subclavicular or cervical region, and it is the more certain and durable in its operation the nearer it is thrown in to the points where the patients complain most of the sensation of irritation and tearing which constitutes the first link of the reflex chain that ends in the cough. Thus, in laryngeal phthisis, the effect is greatest when the injection is made at the sides of the larynx; as it is in circumscribed pleurisy or bronchitis at the apex, when inserted into the painful or tender intercostal spaces. It is rare, under such treatment, for the cough not to be cut short at once, however violent, intense, and obstinate it may have proved to be. The respite is usually a prolonged one, especially if the patient do not become too soon accustomed to the use of the remedy. A great deal is done if the distressing morning and evening paroxysms can be thus prevented. Mere distilled water would suffice, but a few drops of the laurel-water should be added, in order to deceive the patient, for his own good; and for the same reason it is well to call the injection a solution of bioxide of hydrogen. This addition causes a little temporary irritation on injection, which also favorably impresses the patient.

The New German Pharmacopœia.

This national work, intended for the whole German empire, is in a forward state of preparation. Foreign exchanges inform us that it will

be published in the German language, including the heading of each article, to which, however, the Latin titles will be added. The title of the new edition will be *Arzneibuch des Deutschen Reiches.*

The editors have treated the question of striking out unnecessary drugs and preparations in a very radical fashion It is said that of 797 articles in the *German Pharmacopœia*, no fewer than 370—that is to say, nearly a half—are eliminated by this Commission. Among them are acetum colchici, aconitin, ammonium carbonicum pyro-oleosum, valerianates of bismuth and of quinine, bromine, prepared shells, elemi, dry and inspissated ox-gall, several preparations of iron, kino, logwood, mastich, acetate of morphia, santonate of soda, oxymel of colchicum and of squills, guaiacum and scammony resins, lactate and valerianate of zinc, etc.; as well as about half of the hitherto officinal distilled waters, plasters, extracts, ethereal oils, tinctures, and ointments. They are proceeding much more cautiously in adding new agents to the pharmacopœia. They have added salicylic acid, nitrite of amyl, apomorphin, physostigmin, jaborandi, and pilocarpin; on the other hand, they have rejected condurango, coto bark, quebracho bark, leaves of eucalyptus and the preparations thereof, araroba and chrysophanic acid, butyl-chloral, bromide of camphor, gelsemium, etc. In the matter of antiseptic dressing, materials have been added, as concentrated carbolic solution, and carbolic water prescriptions formulated for absorbent cotton-wool; catgut in three strengths, gutta-percha paper, thymol, and acetate of alumina.

The Nutritive Powers of Koumiss Illustrated.

An extraordinary illustration of the nutritive powers of koumiss was recently brought before the Medical Society of London.

Dr. H. Sutherland read notes of this case. The patient, a girl aged 24, on admission, had been for five years under his care at St. George's (Hanover Square) Dispensary. One year and seven months ago vomiting commenced; the attack came on at first only once a fortnight, but lately it occurred always once, and sometimes five or six times, a day. As far as could be ascertained, there was no organic disease of the stomach; no tenderness on pressure, cachexia, nor any other constitutional symptoms. Every known remedy was tried to allay the vomiting—bismuth, opium, hydrocyanic acid, creasote, carbolic acid, hyposulphites, etc.—without any satisfactory result. All attempts to cure the case by dieting had failed; and the patient could keep nothing on the stomach, as food, except koumiss, which she had taken for sixteen months. She was, however, able to retain a quinine and orange mixture, and also sherry in small quantities, but brandy made her sick immediately. The uterus was not displaced.

Mutual Aid Associations.

The plan has at various times been brought forward to organize inside the medical profession a mutual aid association. Such a one is established in this city, and others in other limited areas, and seem to work well. Life insurance experts predict that all such plans will not succeed, for various reasons which they advance, as may be seen in the last Annual Report of the Provident Life Insurance Company of Philadelphia.

An ardent supporter of such an association is Dr. Frederick Horner, Jr., of Virginia. In a report which he presented at the last meeting of the Virginia State Medical Society he says: "We are unable to recognize an objection to a trial of the experiment to raise funds to be applied for the relief of the destitute. Our medical brethren furnish no exception to the accidents, financial distress, and even immoralities, incident to human life, and at death not unfrequently leave their families without support or the resources of education. Let our effort be to relieve this class."

Instance of Rapidly Fatal Syphilis.

A striking example of rapidly fatal syphilis was lately reported to the Glasgow Pathological Society:—

Dr. Robertson showed the brain of a stout man, aged thirty-two, who had become hemiplegic several weeks after acquiring syphilis; the primary sore and a secondary rash being present at the time of death. The necropsy did not reveal any morbid change in the chest or abdomen. The left internal carotid artery, at its bifurcation into middle and anterior cerebral, was obstructed by a thrombosis, and the wall of the vessel was thickened. The left anterior and middle lobes were much softened. Dr. Robertson considered the diseased condition of the vessel to be due to the syphilitic poison. It was rare to find such arterial change while the primary sore was still present, though it occurred occasionally with ordinary secondary symptoms.

The Detection of Carbon in the Air.

A new method of estimating the amount of organic carbon in the air was recently laid before the Chemical Society of London, by Drs. Dupré and Hake. The carbon is converted into carbonic acid by passing the air over heated oxide of copper; the carbonic acid thus produced is absorbed by baryta water, the carbonate is converted into sulphate, which is weighed. The carbonic acid present in the air as such is estimated in a similar way and deducted. The mean quantity of organic carbon in 10 litres of ordinary London air was 0.000154; Boussingault and Verser found ten times as much. The authors also refer to the results obtained by Pettenkofer in his well-known experiments on the elimination by animals of H and CH_4. Pettenkofer seems to have entirely neglected the organic carbon in the atmosphere, and thus his results require very important corrections.

The Striation of Muscular Fibres.

The cause of the striation of voluntary muscular fibres was not long since discussed before the Royal Society of London, by Mr. John Haycraft. He showed that all the cross striæ observed are due, not to any differences of structure along the fibre, but simply to the *shape of the fibre* itself. The fibre is not a smooth cylinder, but is ampulbated, alternate ridges and depressions occurring with beautiful regularity across its length. The striæ correspond with these in position, and are caused by their action on the transmitted light. He showed theoretically how this must be so, and illustrated it with a model of the same shape as the fibre, but of uniform structure, which exhibited, down to the minutest detail, the cross striæ of the fibre itself. He then showed the true explanation of the action of staining agents and of polarized light.

Injury from Earrings.

At the Therapeutical Society of Paris, in December, Dr. C. Paul stated that, simple as is the operation of piercing the ears and inserting the ring for earrings, it not unfrequently—and especially in scrofulous subjects—gives rise to most serious effects. Since his attention was called to it about fifteen years ago, he has been able to collect, without difficulty, one hundred and twenty such cases in which scrofulous eczema or ulceration has appeared, deforming the lobule or cutting it through as clean as the chain of an écraseur, and leaving unsightly cicatrices. Union in these cases is effected with difficulty, and renewed piercing of the lobule is followed by the same results. M. Féréol has found, in cases where the metallic ring could not be borne, that ulceration may sometimes be prevented by employing a filiform gum bougie.

The Causes of Pneumonia.

On this point Dr. Edwin M. Snow, of Providence, remarks, in a recent report:—

In regard to the causes of pneumonia, it is a mistake to suppose that it is caused by "catching cold," in the ordinary meaning of the phrase. Some other element than cold is necessary to produce pneumonia. It probably frequently depends upon personal idiosyncrasy or constitutional predisposition; foul air may be often the cause, and especially the foul air of the sick room; sometimes there seems to be a general atmospheric (epidemic) cause that produces a great amount of the disease. Some persons have thought they could trace a connection between pneumonia and the natural malaria of so-called malarious districts.

Correspondence.

Bellevue Hospital Medical College Weakens; and Why?

Ed. Med. and Surg. Reporter:—

From the late Announcement of this honored Institution, we learn that the high vantage ground taken in a previous circular touching the preliminary examination of applicants, and the three-term course of lectures requisite for its honors, have been receded from, thereby implying that they have not been sustained by the Profession, as indicated by their patronage, in this desired step of progression. Can this really and truly be the cause? We do not question their honesty or integrity in the declaration, but simply the causes assigned therefor. All the utterances of county, state, municipal and national Medical Associations touching the raising of the standard of medical education, and the status of graduation, fail to sustain this cause of weakening; and we feel as if it was a reproach upon the profession, because of their inability to appreciate the efforts made by Bellevue for the advancement of medical education.

No man, whether now in the profession, worthy of the name, or seeking to enter therein, but glories in the high standing of the school that issued or may issue his diploma. as alike the purity and exaltation of his profession.

For our part, at the mere thought or mentioning of the University of Pennsylvania, our *alma mater*, our bosom heaves with emotional pride in the character and standing of this time-honored institution. We sought its honors because of the requisites thereto, and however high these requisites are made, a hearty response goes from us.

Those medical institutions whose efforts have been directed towards the exaltation of the profession merit the approbation of that profession, and as the *Professors* therein are, such will be the estimate of the profession at large. Especial pride has been manifested by the medical profession generally, almost amounting to exultation and vanity, in the success and status of Bellevue. We are not ashamed to confess that the writer shares in that spirit largely; for this college is manned by skilled genius and great learning combined; and as the Hospital is the greatest charity of a great city, so the college is the fruit of the noblest spirits of the profession. Then let us see if there are not other and more plausible reasons why this noble institution recedes from its advance. Turn to their Announcement of the previous year, and you find an *embargo*, a *prohibition*, laid on the entire medical body, whether hoary from field service or crowned with younger honors in medical science, until you shall pay tribute and purchase their tickets for the privilege of attending their lectures. No matter, then, whether a graduate of any other school of even so high repute, of five or fifty years' standing, if you perchance may wish to listen to their teachings, or drink from the stream that flows through Bellevue, you must pay for the privilege or go thirsty. There ever is and must be a reciprocal courtesy and influence existing between the profession and our schools, as the friends of the several schools favor applicants to the school of their respective choice. There is a degree of civility and respectful deference existing between the *schools* and the *profession*, and the students and under graduates and the schools themselves. The status of the *profession*, and the professors in schools, other things being equal, demand like civility and complaisance.

The proprieties of official life, and the observance of fraternal decorum, should characterize the intercourse of our noble—the noblest and most self-sacrificing of human callings. We imbibed this spirit from our departed masters, and shall ever maintain that medical knowledge, to the regular profession, is common property, without being patented, trade-marked, or ticketed to those entitled to receive the same; that less than this would be uncivil and discourteous, whether arising in the walks of the busy practitioner or the more fortunate and gifted occupant of a professorship in our schools. When Bellevue took this forward step, did she not hamper her progress by this indiscriminate prohibition on the profession at large; failing to observe that deference due thereto which is not due the under graduate and student at the school.

Louisiana, Mo. JNO. S. PEARSON, M.D.

Foreign Bodies in the Stomach.

ED. MED. AND SURG. REPORTER:—

In the REPORTER of January 1st, 1881, No. 1, we find an article entitled "Curious Accumulation of Foreign Bodies in the Stomach." I have also found great difficulty in forming a diagnosis. I once made a sad mistake. which I discovered after death, which was due to the accumulation of watermelon seed in the stomach. Such experience is never forgotten.

November 14th, 1878, I was called in haste to see Mr. B., a young man of 27 years, very stout, the son of a farmer. Found him suffering great pain, walking bent forward, round his room, screaming for help, and at intervals of three to five minutes, would fall upon his knees, pressing his hands against the bowels, throwing his body backward and forward, expression of extreme agony. More melon seed. Obstruction. Ordered him held. Examined him best I could. Slight pressure upon the epigastric region over the pyloric end of the stomach produced unendurable pain.

Upon inquiry I learned, November 10th, while working at the sugar house he had a chill, and on the 11th diarrhœa, which caused him to stop work and go to his employer for advice, who, by the way, was an excellent M. D., who gave him morphine and quinine, which gave relief, and he continued work; 12th, chill again; asked permission to go home, and left, with a supply of quinine, to prevent return of chill. November 14th, three P.M., at home, chill followed by the above pains, etc.: all the history I could obtain. Nothing in the way of medicine aided nature. 16th, at four A.M., K. M. Clark, M.D., was sent for at my request, and at ten A.M. arrived to find my patient asleep for the first time. At eight o'clock that morning the bowels acted, and there passed a large amount of hard clay-looking fæces, mixed with peas, some perfectly whole, which we supposed to be the cause of the trouble, and left him to nature's sweet repose. That evening at three o'clock, chill returned, and followed by similar symptoms, not so severe; vomiting gave relief. 17th, no change, some fever. 18th, pain now and then; fever continues. 19th, 8 A.M., no fever, resting well, passed a good night; 4 P.M., chill symptoms returned again; commenced vomiting and nothing would be retained; and when the stomach became empty, all pain would be gone. Thus my patient remained, chill. followed by the same pain every third evening. And during the whole time, from the 14th of November to the 15th of December, you could feel a distinct. hard mass at the pyloric end of the stomach, which I said was inside, but was unable to prove until 4 o'clock, December 15th. Then the mass came away, being three and a half by one and a half inches, covered with mucus resembling a thin membrane, that nature had thrown around, to prevent injury and shield the canal, in the centre of which was found five large seed which we recognized as persimmon seed. Patient then remembered the time and place of eating the same, which proved to be October 20th; remained until November 10th, producing no inconvenience; making their exit December 15th.

Patient now married and has never needed medication a day since or before. There must be similar cases, but I am unable to find them on record. Being out in the country, cut off, so as never to have the pleasure of conversing with my brother physicians, I am always interested in reading communications from rural M.D.s, and hope this may be the means of more from them.

Babb's Bridge, La. J. A. JOHNSTON, M.D.

Veratrum in the Opium Habit.

Ed. Med. and Surg. Reporter:—

The article in the Reporter of November 8th, 1879, on veratrum and its uses, brought me a correspondence from the Pacific to the Atlantic coasts, and all but two of the letters had reference to the above habit.

To these, in the main, I replied in detail. It will, perhaps, at this time serve a better purpose to illustrate from the life, and to show that by voluntary or forced seclusion, with judicious treatment, relief is at least possible, and hope may be offered to the enthralled; for few cases offer less hope than the one whose case is here recited.

July 30th, 1880, at 9 o'clock at night, came to my door a young man of twenty-four, groaning violently, as if in acute pain, and one with seemingly as natural tendency to all forms of perverse evil, as water to run down a decline.

He had in the morning taken, as his last dose, four grains of morphine and two ounces of laudanum. I refused him any help, promising, however, to see him in the morning. This I did, and found that he had spent a night of restless and tremulous horror.

He consented then to submit himself to entire seclusion in his room, where he would second every effort made to rid himself of his opium, in which effort, from the beginning of the attempt, encouraged by his family, he persisted.

He was ordered five drops of fluid extract of veratrum every four hours, till nausea ensued, then the same dose at longer intervals, concentrated nourishment, and the absolute withdrawal of any opiate.

In forty-eight hours the stomach had become intolerant of anything, circulation depressed below natural standard, volume fair. Black coffee, ammonia and capsicum were then ordered, and the veratrum withdrawn. All of these the stomach rejected. He was now groaning and tossing, mourning and complaining. No sleep seemed possible to him. From this time the case marched through seventy-two hours more of like agony. Nausea, vomiting, intense restlessness, growing rapidly weaker. At the end of one hundred and twenty hours the pulse had become a thread, by reason of this sleepless and innutritious agony.

He was now too weak to move, and laid on his left side with knees drawn up, his whole surface cold, and leadish almost in color, his respiration rapid, with a faint moan, and occasional gasp to supplement his breathing, wasted almost to a skeleton by the fearful struggle, and the odor from his body absolutely cadaveric.

The hour for action and triumph had now come. I inserted hypodermically half a grain of morphine. For one hour quiet was restored, the surface was warm, the stomach retained milk, reaction was complete.

He had, for twenty-five nights consecutively, from this time, one-fourth grain of morphine at bedtime, then no more, and has just left my office, March 2d, robust and hearty, freed from the habit, and, as he tells me, from any desire for its use.

E. H. Sholl, M.D.

Gainesville, Ala.

Frostbite.

Ed. Med. and Surg. Reporter.—

During the low temperature that has prevailed this winter the physician has had an opportunity to study the effect of cold, not alone on his own system, but on that of others, who, by misfortune, or other causes, have failed to use proper precautions, and have been obliged to apply to him for relief. We are all aware that the pathological conditions produced by an excessively high or low temperature are almost identical; yet the treatment must differ in each of these conditions; and while the experienced physician may have the treatment for these conditions crystallized into tried and trusted formulas, properly labeled and stored away in the brain ready for emergencies, yet the inexperienced, when called to treat a frostbite, or if the parts have sustained greater injury, may search in vain, unless he be the fortunate possessor of an extensive library, for a thoroughly reliable remedy, or combination of remedies, that will not bring disappointment and often danger to his patient. No doubt many can recall instances that have fallen under their observation, of terrible loss of life and limb, that might have been saved if properly treated. Again, the temptation to amputate in these cases before persevering attempts have been made to save the part is very great, as the fact exists, that with the public the operative surgeon is greater than the conservative, and this, often, it may be unconsciously, is an important factor in determining the time to amputate.

In February, 1879, I was called to amputate the greater part of the left hand of a man aged forty-five, that had been frozen four weeks before, and had been treated by applying poultices of flaxseed meal and was completely gangrenous. He made a good recovery from the operation. The same month the treatment I shall detail saved the foot of a young man I was called to attend, who was exposed to a very low temperature all night, without overshoes, and a very thin pair of boots on his feet, they having been thoroughly wet in the evening; the left foot seemed to be more affected than its fellow, being perfectly black in color, with complete loss of sensibility. I kept the feet constantly saturated with

℞. Bal. copaiva
Sp. turpentine, āā equal parts,

and thoroughly covered with absorbent cotton. I have used this treatment for years, and it has always pleased me. It may be applied in an ulcerated or even gangrenous condition, has a soothing feeling to the patient, and rapidly restores the circulation to its normal condition.

Saunemin, Ill. H. E. H. Barnes, M.D.

Treatment of Pneumonia.

Ed. Med. and Surg. Reporter:—

Years ago, when I first commenced the practice of medicine, I at once subscribed for the Medical and Surgical Reporter and have ever since taken it, and drawn inspiration from its pages. Among the first articles which came under my notice and which particularly attracted my attention by their forcible style and the posi-

tive conviction that they carried with them, were those by Dr. Hiram Corson, on the treatment of measles and scarlet fever, with ice, etc. I was so much pleased with the result of carrying out his treatment in those diseases, that when I have seen an article headed by his name, I was able to read it carefully with the positive result of getting some practical and valuable information. You will notice that what Dr. Corson says is *practical*, to *the point*, and backed by a large personal experience.

After reading the above, you can judge how eagerly I devoured his recent valuable papers on pneumonia. I studied them carefully, and became convinced that there was the ring of truth in them. I decided at my first opportunity to fully test the treatment, and with the most gratifying results to myself and patients. You must understand that in this village pneumonia is very fatal under the old treatment, and with the best care and the best treatment I could give, enlightened by the very best teachers of the day, my results were nothing to be proud of, and I got so that I actually dreaded to be called to a case of this disease. Since Dr. Corson's articles have appeared I have had five cases, one of them an old man seventy-three years old, and one eighty-two years old, the other three under thirty. *Every one recovered*, and two aborted the third day after the treatment commenced, and in a week resumed their work in one of our shops. The other three, including the seventy-three year case, ran a mild course and made a rapid recovery. These were all typical cases of pneumonia, with all the characteristic symptoms, roseola, sputa, etc., and were fair prototypes of the cases that had originally been so difficult to cure, and which, if a cure was effected, left the patient with a crippled lung and constitution for life. I want to be placed on record as standing fairly and squarely by Dr. Corson's side, fighting the good fight in favor of health and life.

To him be all *honor* and *glory* (for he will get it), for using and infusing new life into an old treatment. WM. C. WILE, M.D.

Sandy Hook, Conn.

The German-English Medical Dictionaries.

ED. MED. AND SURG. REPORTER:—

Though your criticism of Barnes' German-English Dictionary, in the No. for February 26th, 1881, is, in the main, correct, you say that he "in a certain measure supplants" Cutter's Dictionary.

It is true that Dr. Barnes has copied all but half a score of my words, with their definitions, punctuation, etc., but I fail to find that he has materially increased the number of words that would be of service to a medical reader. Moreover, he has suppressed the genitive and plural terminations of the nouns, as well as the auxiliaries of certain verbs—information which is often indispensable in a dictionary of German. By this means he has gained room for his "needless additions, not particularly or at all scientific." The two books contain the same number of pages.

A careful examination of his book shows a great many inaccuracies (over a hundred), such as wrong spelling, misplaced and omitted Umlauts, etc., many of them quite confusing to one not familiar with the German.

My dictionary is an original work, an alphabetical list of the medical terms I met with in reading German books and journals, during twenty years, with their definitions. It was not written to make *money*, and I hoped to increase the usefulness of the book as fast as the plates paid for themselves. For this reason I ask that the press and the profession discountenance Dr. Barnes in his shameless piracy.

New York City. G. R. CUTTER, M.D.

[We quite agree with Dr. Cutter, that Dr. F. Barnes committed a downright dishonorable act by appropriating the German Dictionary. By the by, the Edinburgh *Medical Journal* proves, conclusively, that Dr. Barnes is very ignorant of German, and translates it very incorrectly.—ED. REPORTER].

Tinctura Rusci.

ED. MED. AND SURG. REPORTER:—

I notice in your issue, March 5th, a formula, given by the *Am. Journ. Pharm.*, for tinct. rusci, as recommended by Prof. Kaposi, for ringworm. The explanation given there is entirely erroneous. Prof. Kaposi simply means the oil of betula alba, or birch oil, oleum betulæ empyreumaticum, oleum rusci, the tar of the root, wood and bark of the birch tree. The formula for tinct. rusci is as follows:—

℞. Olei rusci, 50
Æther. sulph.,
Spr. vini āā 75
Filtrat. adde,
Olei lavandulæ 2. M.

Fredonia, Wis. Dr. J. H. VOJE.

NEWS AND MISCELLANY.

COLLEGE COMMENCEMENTS.

University of Pennsylvania—Medical Department.

The regular Commencement for the 115th annual session of the Medical Department of the University of Pennsylvania (including the Departments of Medicine and Dentistry) was held March 15th, in the Academy of Music. The attendance was very large, the aisles on the ground floor being crowded with persons obliged to stand during all the exercises. The graduates of both departments, numbering 162 in all, and wearing the classic hat and gown, were assigned to seats in the orchestra, and the ample stage of the Academy was filled with the members of the Board of Trustees, the Board of Faculty, the Alumni Association and invited guests. Provost Pepper presided. He and the members of the Faculty were also clad in the collegiate hat and gown.

After several selections had been played by the orchestra, the officers of the University and the graduates entered from the green room upon

the stage, the graduates marching thence to the orchestra. Prayer was then offered by Rev. Dr. O. H. Tiffany, pastor of the Arch Street M. E. Church, after which the degree of M. D. was conferred by the Provost upon the graduates of the Medical Department.

The prizes were announced by Dr. Tyson, Secretary of the Medical Faculty, and awarded, as follows:—

A prize of $50, for the best essay upon medical subjects, to each of the following graduates, in the order of merit of their theses: J. P. C. Griffith, O. C. Robinson, G. E. De Schweinitz and L. J. Lautenbach, all of Pennsylvania. Honorable mention was made of the theses of T. D. Dunn, W. A. Edwards, M. F. Gerrish, J. B. Gibbs, H. H. Herbst, Guy Hinsdale, James Kingsbury. Moyses Marondes, E. F. Nunez. B. O'Brien, E. P. Raab, E. T. Shelly and H. K. Weiser.

Distinguished merit was announced for the theses of Louis Brose, G. B. W. Field, R. B. Hammer, J. B. Scott, H. D. Speakman and W. N. Whitney.

The gold medal anatomical prize offered by Dr. H. L. Hodge was awarded equally to Thos. D. Dunn and G. E. De Schweinitz, and "distinguished mention" was made of M. T. Weber.

Prize of thirty dollars, for the best record of anomalies found in the anatomical rooms, was awarded to Guy Hinsdale, of New York.

The "Morbid Anatomy Prize" was awarded to E. H. Dickenshied, Dr. N. M. Miller receiving honorable mention.

Drs. G. E. De Schweinitz, J. V. Scott, S. J. McGrew, J. J. Buchanan, M. Marcondes, L. D. Brose, Thos. D. Dunn, W. C. Gayley, J. P. Griffith, W. A. Edwards. Jas. Kingsbury, Alex. Marcy, Jr., Chas. W. Kollock, J. P. Tuttle, J. R. Duffield, E. B. Angell, J. S. Hennershotz, J. B. Gibbs, W. E. Berkaw, T. C. Detwiler, W. G. Knittle, J. A. Lopez, J. H. W. Young, M. J. Weber, Dan'l Longaker, A. B. George and H. F. Weaver were announced as the "Honor Men" of the class, having all attained an average of over ninety.

THE DENTAL DEPARTMENT.

The degree of Doctor of Dental Surgery was conferred upon forty-seven graduates.

The following award of prizes was announced by Dr. Charles J. Essig, Secretary of the Dental Faculty:—

Set of Instruments, presented by S. S. White, for the best thesis, to C. T. Howard; with honorable mention of the essays of S. R. Wing and K. P. A. Kaas.

Prize of dental instruments, presented by S. S. White, for the best specimen of laboratory work, to W. C. Wendel.

Prize of gold medal, presented by Dr. Essig, for skill displayed in the laboratory, to R. H. Kimball.

Gold medals, presented by Prof. E. T. Darby, for the best specimens of gold fillings in the mouth, were awarded to A. J. Kutz and C. C. Southwell.

Honorable mention was made of the following gentlemen, for averages exceeding ninety:—

Stephen R. Wing, D.D., Herman L. Reinecke, Cyrus T. Meaker, William W. Steward. Benjamin F. Place, Earle P. Hawes, Charles T. Howard, Boyd G. Saunders, Victor M. Smith, Charles C. Southwell, Theo. V. Ketcham, Burr T. Mason.

The valedictory address to both the graduating classes was delivered by Professor Horatio C. Wood, A.M., M.D., and, after the distribution of the floral tributes to the graduates, the exercises were concluded.

Woman's Medical College.

The twenty-ninth annual commencement of the Woman's Medical College of Pennsylvania was held at noon, March, 17th, in Association Hall. A large audience was present. Flowering plants and palm trees decorated the front of the stage. The graduates, all wearing black silk dresses, occupied the first row of the orchestra, the three rows of seats in the rear being reserved for the students of the College. On the stage were seated Judge Peirce, who acted as President pro tem. in the absence of President Perot; Professor Samuel D. Gross, Bishop Simpson, the Corporators of the College, and the members and auxiliary members of the Faculty of the institution. Carl Sentz' orchestra, in the gallery behind the stage, played several selections before the entrance of the graduates. The exercises were opened with prayer by Bishop Simpson. The degree of M.D. was then conferred by the President upon the following graduates from the States named:—

Pennsylvania—Mary Hallowell, A.B., Rebecca S. Hunt, A.B., Hannah J. Price, M. Elizabeth Reifsnyder, Florence Preston Stubbs and Mary Willets, A.B.

Ohio—Mary Jordan Finley, Georgietta T. McClelland and Minnie Palmer Washburn.

New York—Mary W. Case, A.B., Caroline A. Hemiup, B.A., and Martha M. Waldron, A.B.

Massachusetts—Ellen E. Brown and Ella L. Dexter.

Missouri—Mary A. Kolbe.

Indiana—Emma V. P. B. Culbertson, A.B.

New Jersey—Hannah H. Johnson, A.B.

New Brunswick—Alma A. Lapham.

New Hampshire— Addie H. McDaniel.

In conferring the degrees, Judge Peirce briefly addressed the graduates in terms of congratulation, encouragement and advice.

The diplomas having been presented, Professor Rachel L. Bodley, M.D., Dean of the College, delivered the valedictory address, in which she reviewed the statistics and development of the medical education of women, and their success in the profession. This address has so much of interest that we give its principal headings in detail, elsewhere.

Philadelphia College of Pharmacy.

The sixtieth annual Commencement of the Philadelphia College of Pharmacy was held March 14th. The Proctor prize medal, together with the Alumni gold medal, were presented to Louis Genois, of Louisiana. Prizes for proficiency were also awarded to W. F. Jenks, of Pennsylvania, materia medica; W. C. Smith, of Iowa, pharmacy; Gustav Adolph Otgen, South Caro-

lina, chemistry, and Samuel W. Miller, Pennsylvania, manipulation. Professor Joseph P. Remington delivered the valedictory, and the exercises were brought to a pleasing termination by the presentation of a pair of fine prescription scales to Professor Remington, by J. W. Swope, on behalf of the Zeta Phi Society. The degree of Graduate in Pharmacy was conferred by the President of the College on 140 graduates.

Leprosy in the United States and Sandwich Islands.

We have been requested to insert the following:—

At a meeting of the New York Academy of Medicine, held January 20th, 1881, the following resolution was adopted:—

Resolved, That a Committee be appointed by the President to investigate the extent to which Leprosy prevails in the United States.

The President appointed as such Committee, Drs. H. G. Piffard, F. R. Sturgis, and G. H. Fox.

The Committee are desirous of ascertaining the actual number of Lepers in this country at the present time, and to that end respectfully request any physician who may know of the existence of a case in his neighborhood to communicate the fact to the Chairman of the Committee, at No. 10 West 35th Street, New York.

Now that leprosy in the United States is attracting some attention, the report of Dr. Chas. Neilson, who has succeeded Dr. Emerson as superintendent of the leper settlement on the island of Molokai, will be read with interest. At the close of the year 1880 there were six hundred and nine persons in the settlement, and one hundred and sixty-one had died during the year. Nine children were born of leprous parents, and six deaths occurred under one year of age. Dr. Neilson observes that efforts to improve the hygienic condition of the lepers meet with no aid from them, a marked feature of the disease being a condition of apathy and despondency. The government has made liberal provision for the afflicted, in providing good shelter and an ample supply of wholesome food. Among the remedies in use, an oleo-resinous substance, known in commerce as gurgun oil, is considered the most valuable, especially when combined with lime-water. The treatment is, however, empirical, and is addressed rather to special symptoms than to cure of the disease. Leprosy is regarded as undoubtedly contagious.

Another Charter Annulled.

After eight months of litigation in the Courts, the Commonwealth secured, on March 15th, a decree of ouster in the quo warranto proceedings against the Philadelphia University of Medicine and Surgery. This result was brought about by agreement of counsel on both sides, the following papers having been filed in the Court office: Commonwealth of Pennsylvania ex relatione the Attorney General vs. Ingraham et al. C. P., No. 3. June T., 1880. No. 614.

And now, March 15, 1881, the defendants served * * * say that they disclaim any intention in the future to exercise any corporate right, and that they consent that a decree of ouster may be entered as of this date, without costs, the Commonwealth expressly recognizing all diplomas granted in accordance with the terms of said charter, and validating all past acts, the decree prohibiting only the exercise of any future corporate act.

This medical college was known as "Dean Miller's."

A Righteous Decision.

It is gratifying to learn that the New York Court of Appeals has dismissed the appeals of the insurance companies in the Dwight cases, seven in number, with costs. Colonel Dwight, of Binghamton, was heavily insured in several companies, and some of them refused to pay the insurance after his death, alleging that "not only were they deceived by Mr. Dwight, as to his state of health and occupation, but that his death was either caused by his own hand or he procured the taking of his life with a design to defraud the companies."

It was a simple endeavor to get out of paying just liabilities.

The Siamese Twins Outdone.

An Italian couple, Tocci by name, are at present exhibiting at Vienna a most remarkable specimen of their progeny, a pair of twins named Jacob and Baptiste. These boys are grown together from the sixth rib downward, have but one abdomen and two feet. The upper part of the body is completely developed in each; their intellectual faculties are of a normal character. Each child thinks, speaks, sleeps, eats and drinks independently of the other. This independence goes so far as to admit of an indisposition of the one without in the least affecting the other. They are over three years old, in perfect health and seemingly in excellent spirits.

St. Helena as a Health Resort.

—We learn, in the *Bulletin* of the National Board of Health that, in his report of January 22d, United States Consul H. J. Crouch observes that during the previous week the only death reported was that of a Spanish sailor, who died of "Java Fever;" no deaths in the city of Jamestown, which has a population of 6210. The streets are cleaned and swept daily, and the excellent sanitary condition, with the favorable climate, renders this one of the most salubrious places in the world.

Items.

—A private letter from Danville, Pa., states that the loss by fire in the State Hospital for the Insane, near that place, amounts to about four hundred and fifty thousand dollars. There were twenty-two wards, and fourteen of these, with the central building, were destroyed. The structure was very far from being fireproof, and in rebuilding it an effort will be made to correct the mistakes of construction exposed by the fire.

—In consequence of an outbreak of the plague the Government of Egypt has issued a notice of quarantine against vessels from the Persian Gulf.

—A resident of Columbus, Ohio, has brought suit for $50,000 damages against a relative who had applied to the Probate Court for the appointment of a guardian for him on the ground of alleged imbecility.

—The Committee on Public Health in the Michigan Legislature has reported favorably upon a bill requiring liquor drinkers to take out licenses, and providing penalties for selling liquor to persons not thus licensed to buy.

OBITUARY NOTICES.

—John Harris, M.D., Consul of the United States at Venice, died there February 21st. He was in his 89th year, and was appointed by ex-president Grant. Deceased was at one time engaged in the medical profession in this city, and was highly esteemed for his many excellent traits of character.

—Dr. John Dennison Russ, a distinguished philanthropist, died March 1st, at his residence, in Pompton, N. J., in the eightieth year of his age. Dr. Russ was born at Chebacco, now called Essex, in the State of Massachusetts, in the year 1801. He graduated at Yale College in 1823, and afterwards studied medicine at Bowdoin College. He afterwards spent three years in Greece, and on his return devoted much time to the instruction of the blind. Most of his later life he spent in New York city.

—M. B. Mosser, M.D., died at his residence in Mechanicsburg, Pa., March 14th, after a protracted illness, in the 45th year of his age. He graduated from Jefferson Medical College in 1862, soon after entered the army and served as Acting Assistant Surgeon during the war of the rebellion, in field and hospital, the latter in Haddington U. S. General Hospital, of which he was executive officer, until that institution was closed in the fall of 1865. He was a member of the American Medical Association, Medical Society of Pennsylvania, and Cumberland County Medical Society. He has made several contributions to medical literature, and was respected by all who knew him.

QUERIES AND REPLIES.

Size of Brains.

MR. EDITOR:—Dr. Faust, in your publication of March 12th, 1881, Queries and Replies, gives the weight of the largest brain on record as sixty-five ounces; on page 497, vol. xxvii, of MEDICAL AND SURGICAL REPORTER, he can find one noted as exceeding sixty-seven ounces. For the smallest on record, of a female, aged forty-two, whose weight of brain was two ounces and five grains. Let him look in MEDICAL AND SURGICAL REPORTER, vol. xi, page 355. The weight of brain of several distinguished men can be found, MEDICAL AND SURGICAL REPORTER, vol. xxiii, page 40, where Cuvier's is quoted at 64.5 ounces. W. PENNINGTON, M.D.

Basking Ridge, N. J.

Calomel and Chlorate of Potash.

Several further replies have been sent in reply to this query (January 29th). Dr. Divelbis, of Kansas, states that he frequently combines them, and by so doing obtains the desired effect of the mercury by the exhibition of smaller doses. No signs of poisoning have ever manifested themselves.

Dr. Millard, of California, also writes that the chlorate will retard the period of salivation when combined with calomel.

Dr. N. V. S., of Ohio. There is no recent monograph on the pathology of fever. Much has been written on it in the later general treatises on pathology, and also in the journals.

Student asks:—

1. What is meant by the term clay colored?

2. How are these two statements, found in Flint's *Physiology*, p. 26, to be reconciled? "It appears that all circumstances which favor exposure of the blood to the air hasten its coagulation," and "The blood will coagulate more rapidly in a vacuum than in the air."

Ans.—Clays differ in color materially, but the term generally is understood to mean a yellowish white.

2. No reconciliation is needed. The statement is simply one of observed facts. The formula you inquire about appears to be correctly printed.

Dr. T. M. M. writes:—

"In all but liquids I can with little trouble convert grams and centigrams, etc., into grains, scruples and drachms; but when it comes to measuring water, tinctures, and fluid extracts thus, I do not know how to do it. I write, therefore, to ask that you publish a rule for this."

Ans.—It is sufficiently accurate to say that one cubic centimeter equals fifteen minims; four cubic centimeters = one fluidrachm. The gram and the cubic centimeter may be considered as equal quantities, except the liquids be very heavy or very light.

MR. EDITOR: I wish you, or some of your many readers, would give me some suggestions in regard to lead colic. The patient is a painter, thirty-one years old, and has been in the business sixteen years. For the last year he has not been painting. I have given him the usual treatment, and can relieve him temporarily, but it returns in a few days.

Another obscure case is that of a patient, female, forty-six years old; she has ceased menstruating three years. For two and a half years she has had intestinal pain, spasmodic and intense, unless under the influence of anodynes. I have nearly exhausted the materia medica, with no relief. J. M. B.

Indiana.

DEATHS.

COX.—In Kalamazoo, Michigan, on February 28th, Thomas C. Cox, M.D., in the 40th year of his age.

MONELL.—On the evening of March 7th, at Greencove Springs, Florida, Dr. Joseph S. Monell.

WADE.—At his late residence, in Cincinnati, Ohio, Dr. E. D. Wade, in his 59th year.

HARRIS.—John Harris, M D., consul of the United States of America for Venice, in his 89th year.

BOYER.—At New Orleans, March 12th, of paralysis, Dr. D. P. C. Boyer, aged 56 years.

PIEPER.—At his residence, No. 9 St. Mark's Place, March 10th, Dr. William L. Pieper, aged 64.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

DISEASES OF THE HEART—CONTINUED.

BY ALONZO CLARK, M.D., LL.D.,

President and Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

I told you, in speaking of hypertrophy, that I would show you a heart that is, probably, the largest that has been noticed in this country. This is the specimen. There are several interesting things about this: first, that it is, probably, the largest heart that has been seen in this land; second, its history is well preserved. I gave you the history in a previous lecture. He could carry this large heart only because he grew up with it. These large hearts, as far as I have noticed, always begin to be diseased in early childhood, possibly in infancy, and the person becomes accustomed to the extraordinary development of it, and so it gives little inconvenience. It grows with his growth, and may attain this monstrous size.

I told you, when speaking of pericarditis, that I would exhibit to you a heart to which the pericardium was attached. You observe here is the pericardium, and it is attached to the heart. The patient had had endocarditis and pericarditis, and this is an instance in which we can pretty safely say we have twenty-two years from the development of the pericarditis till death. You will see the manner in which the pericardium is trying to separate itself from the heart. By just raising up the flap of this pericardium on either side you will see threads running from one side to the other. They have been considerably torn up by handling, but still I think you will notice them better on the upper side. This pericardium, had the man lived long enough, would have been separate. The attachment, as you see, is loose. Then, as a specimen of aortic disease it is extraordinary. Opening the aorta by "its ears," and getting down to the valves, you see they are thick and leathery. They are more than a line in thickness, nearly an eighth of an inch in thickness, and they are much distorted, and they are, you see, quite incapable of performing their office. They feel hard, like sole leather. Then the right auricle, together with the right ventricle, you observe, is somewhat dilated, but very much encroached upon by the septum ventriculorum. The mitral valve is not so very much diseased. That is to say, its offices are not very much hindered. It is thick, scarcely leathery, its posterior valve is contracted. It is contracted considerably, and I am not sure that it would perform its office perfectly. But the amount of disease there is trifling, compared with that which affects the aortic valves. That, I suppose, the boys would call a "bully" heart.

Here is "bully" No. 2. Here, too, has been pericarditis. You observe how rough the heart is. There is something of that thready appearance, not so much however as in the other specimen, in this pericardium. I do not know the history of this case as I do of that, but you observe here is very marked shortening of the valve. That valve is not one-half its proper height, and it would be impossible for its parts to meet in the middle of the artery and prevent regurgitation. In this instance the right heart is more hypertrophied than the left, that is, in proportion to its natural thickness the walls are thicker, and in regard to capacity it seems to be just about as

great as the left. The thickening here is quite remarkable. The tricuspid valve does not seem to be diseased. The aortic valve is firm, and shortened to a certain extent, and here again the posterior more than the anterior curtain of the valve. But the great defects, or rather the principal diseases of the heart, are the hypertrophy, particularly of the right side, and the valvular disease at the aortic opening. The pulmonary valves are about natural.

Here is another specimen of marked hypertrophy, and here again you observe a (septum) of the aortic valve thickened and drawn down. The valves, you observe, are very imperfect, and allowed regurgitation, while the mitral valve is in tolerably good condition. The right ventricle is small, comparatively. It will not hold one-half, it will hardly hold a quarter of what the left will, and that of itself is a kind of disease. The blood can be thrown out from the left heart a great deal more rapidly than it can be received by the right; and the result is exactly the same as when the valves are defective.

I was speaking to you, when we were last together, of dilatation. I had begun to describe to you the peculiarities of that disorder of the heart. We will go on with that, and I will show you at our next meeting a specimen that is rather striking; a dilated heart, in which, if I remember right, all the cavities are dilated, and they are stuffed with hair, so that the heart has about the size that it had in life, and yet in the cuts made into the walls you will see to what a very marked thinness it has been reduced.

Dilatation, I told you. considering it in the sense in which we are using the word now, is a thinning of the walls of the heart. We have hypertrophy with dilatation, in which there may be considerable thickening of the walls of the heart, but this is spoken of by a distinctive name. We now refer to simple dilatation of the heart, in which the walls of the heart, of the left side, come to be little more than a line in thickness. The walls of the right (?) heart are from five to three lines in thickness in the normal state, that is, five at about half an inch from the base, and growing a little thicker toward the apex, and at the apex three lines in thickness. But this heart that I shall exhibit to you on Friday will give less than a line in thickness of any portion of the left ventricular wall.

The first question that presents itself to us is, how can this thinning occur? A good many speculations have been offered in explanation of this occurrence, but I am inclined to think that the German explanation is the best; that it may occur in two different ways: First, by a reflux of blood when the blood is in a non-nutritive state, dilating the natural walls of the heart till they are thinned down to what I shall exhibit to you; the other, that hypertrophy with dilatation may have occurred, and that by fatty degeneration, which I shall explain to you a little further on, the material constituting the muscle of the heart may be absorbed, taken up, carried away, leaving very little but the two serous membranes, the endocardium and the pericardium. That implies, of course, very marked feebleness in the heart's action. Simple dilatation of the heart to the extent to become a disease is a rare occurrence. I have met with two or three cases, and that is all.

The indications of it, the means of recognizing it during life, are both physical and rational. Among the physical signs will be one that belongs to hypertrophy, extended region of dullness. The lungs will be pushed away, in the same way, from their natural position, and in auscultation for the respiration you will find it silent over the dilated heart. That is, the lung is pushed so far away that the sounds of respiration will not be brought to the ear placed in the midddle portion of the pericardial region. There is no palpitation proper. It frequently happens, however, that the patient complains of palpitation. His sensitiveness is increased at the same time that the action of the heart is rendered feebler; though he complain of palpitation you put your hand over the heart, and you can scarcely feel it beat. In one case that I saw, it was very remarkable that the contraction of the heart was in a wave. It was not a sudden contraction of all the muscles of the heart at the same moment, but the contractile effort seemed to pass up under the hand. Beginning below, I could feel the wave pass the length of my hand. That is, so far as it was applied to the intercostal spaces. I could not feel it, of course, through the ribs, but the intercostal spaces being thin, as I exerted some pressure they would indicate to my hand the kind of action that was taking place in the heart.

A feeble beat of the heart, then, with an increased region of dullness, and a consideration of the kind of sound, will be the chief physical signs. The sounds of the heart are changed in relation to each other; the time is changed, or the rhythm, as it is called. As the heart beats naturally, the second sound follows instantly upon the cessation of the first, and then there is a period of rest, about as long as the period occupied by the first and second sounds together. In this condition you are very apt to

have the motion of the heart, or rather the sounds of the heart, resembling the ticking of a watch, the first and second sounds at even distances apart. The first sound is short, scarcely exceeds in duration the second. Tick, tack; tick, tack; in about that relation.

Then the appearance of the patient gives a marked indication of dilatation. The force with which the heart contracts upon the blood is so far diminished that only a small quantity is sent into the arteries at any one beat, at any one time. This does not dilate the arteries, does not keep them of their natural size. They are apt to grow small, therefore, I referred the other day to the filling of the ventricle during the period of rest of the heart. I perhaps should have said the ventricle has no power of dilating itself. but it is dilated by the force that it has impressed upon the blood when it went out from it into the arteries. The residual force of the circulation when the blood returns to the heart is really the dilating power. In that sense it dilates itself. The venous power is considerable, as when we tie the arm to bleed a man the force of the current is such as to throw the blood quite a considerable distance from the arm. This force is not all exhausted when it comes to the right heart, and it is that residual force impressed upon the circulation by the contraction of the left side that opens the right. In this case now, and so contrariwise, the force impressed upon the blood going out of the right side of the heart opens the left ventricle, or causes the left auricle to fill, and thus is really the cause of the filling of the left ventricle. Now, in this dilated heart you have a very feeble force impressed upon the blood when it comes out of either dilated ventricle. It will, of course, flow into the opposite ventricle in an equally feeble stream. It will dilate the veins, because there is not force enough behind to empty them, and you get œdema of the face, of the feet, and of the surface of the body, and you get at the same time enlarged veins; the blood seems to rest in the veins. Of course, it does not absolutely rest, but the current is slow.

The oppression of the breathing is very marked in these cases. It belongs to almost every form of disease of the heart, but is developed earlier, and is, perhaps, more severe in this than in any other, and that depends upon the failing force with which the blood can be circulated through the lungs. There are at least three distinct causes of dyspnœa besides the nervous causes that would produce the same thing. One is, an overcharged or congested lung, or lungs; another, very slow circulation of the blood through the lungs; and the other, some physical obstacle to the dilatation of the lungs by the air entering them. These three conditions all produce dyspnœa more or less severe, and why? You would suppose that, mechanically, they would not act in the same way. Mechanically they do not, but physiologically they do. They each one interfere with the aëration of the blood. When the lungs are congested the blood is circulating slowly through them, and though the blood that is in the lungs may become aërated it is not given to the system with sufficient rapidity to answer the demands, and consequently a sense of dyspnœa. And then, too, when the quantity circulating through the lungs is very small and the current slow, there is not enough aëration of the bulk of the circulating blood, and there is dyspnœa. Then, when both pleuritic cavities are filled with serous fluid, or any other fluid, and the lung room is not great enough, there is not space for very much aëration of blood, and there is dyspnœa. And these three conditions of the lungs explain most of the dyspnœas that occur with the diseases of the heart, and in none of them is that dyspnœa more perceived, more apt to cause suffering, than in this dilatation of the heart. These are the leading facts by which you are able to recognize simple dilatation of the heart, if you should happen to meet it.

With reference to its treatment, I will say a word, because there is something to be said in regard to this that does not belong to all forms of diseases of the heart. I see recommended in some of the text books, and in special papers on this affection, as a means of relief, bleeding; bleeding from the arm. Well, I will tell you my experience. When I was house physician in New York hospital, a man came in in whom we recognized dilatation of the heart, and it was in that particular man that I got that wavy motion of the contracticle fibres of the heart. My principal, seeing how much he suffered, said bleed him. I looked at him with surprise, and said, "Doctor, I would not dare to bleed him. He cannot lose five ounces of blood without dying." "Pooh, pooh?" says he. "If you don't like to bleed him, give me the lancet." He tied up the arm and took the lancet—I was accessory in holding the bowl—and the vein was opened. The man bled a little spurt, it may have been four or five, possibly six ounces, and rolled over on the bed—I had him sit on the bed on purpose—rolled over on the bed and breathed no more. Of course that did not make me very much in love with bleeding for dilatation of the heart. And yet, even in Niemeyer, if I remember right,

it is recommended, but, I suppose, theoretically, inasmuch as bleeding does in some conditions of dyspnœa give relief. But I do not think it applicable to the dyspnœa which arises from dilatation of the heart. Well, then, there is very little you can do. The man cannot take any exercise. He would drop down of dyspnœa if he were to make any great exertion. He may walk about the ward a little, if he is in a hospital, or in his room, if at home; but that is about all he can do. He cannot go up stairs, and can scarcely go down. About all that you can do is to induce him to take as much food as he can digest, with the hope of enriching the blood a little, and delaying the progress of the disease; to give him chalybeates, which will help in this change of the condition of the blood, almost any form of iron that is a favorite with you, it matters very little, for they all go to about the same thing; and create an active condition of the kidneys, to carry off the œdema. This latter is applicable to almost all the forms of cardiac disease where dropsy has occurred. I shall recur to the matter of diuretics by and by.

With these remarks on dilatation of the heart, we will leave that subject and turn to another condition of disease of this organ. You hear a great deal about fatty degeneration of the heart. You will hear a great deal more than you will see. I scarcely see a fat man advanced somewhat in years, who has trouble with the heart, that the attending physician does not say, "Why, Doctor, don't you think he has got fatty degeneration of the heart?" My reply is uniform, "I cannot diagnosticate fatty degeneration of the heart, and I have no right to assume it in any case without proof." You will see where the difficulty lies pretty soon. Fatty degeneration, to the extent of producing real disease, is quite a rare occurrence; occurring, to be sure, now and then, but in comparing it with dilatation and hypertrophy together, it hardly bears the relation of one to fifty.

There are two kinds of fatty degeneration of this organ. One I have sometimes designated as adipose degeneration, or adipose deposit upon the heart. The other is an integral degeneration of the muscle of the heart into fat. The latter is called. commonly, Quain's degeneration, as he was the first to describe it—the author of the anatomy that was very much in vogue twenty years ago. The two are very easily distinguished by the appearance after death. But neither of them can be confidently recognized during life. The latter, Quain's disease, you will be more likely to distinguish than the other. The fatty degeneration of the adipose variety is merely a deposit of fat upon the surface of the heart. I have some better specimens than this, which I can show you, perhaps, at our next meeting, though this is well enough marked to give you an idea of what is meant by it. Always there is some fat upon the exterior of the heart in the pericardium, but you will observe, in examining this specimen, that here it has encroached somewhat upon the muscular element of the organ. The whole heart is covered with a more or less abundant layer of fatty tissue, but chiefly upon the right side. Well, that is the part of the heart that is most commonly overloaded with this fat. You take a portion of this fat and examine it under the microscope, and it will present exactly the same appearance as adipose tissue taken from any other portion of the body—a multitude of cells filled with oil. It is a healthy fat enough, but a dislocation; it is out of place here. It is out of place here, for the reason that, as it becomes abundant the muscular heart becomes weakened. But many persons, no doubt, carry this condition for a considerable time without knowing anything about it. The heart performs its office with fair regularity and with fair force. But in a few instances it will happen that the fatty encroachment is unequal, and it weakens one part of the heart more than another; as, for example the septum, ventriculorum may be just as strong as it ever was, while the wall opposite is weakened. The result is, that the heart sometimes gives way first at that point; at the point where the greatest weakness of its muscular tissue is it bursts itself. I will refer to that again a little further along. This is the heart, then, and you may examine it and see what it means. The fat is very abundant upon the base, but that does not do so much harm as that deposited along the course of the ventricular wall. The heart is also hypertrophied.

I told you the heart beats with perfect regularity, and that it is not enlarged in any such degree as that you can recognize it by physical signs. Well, then, how can you recognize it at all? Well, just make up your minds, now, and forever, that you cannot recognize it, except after death. And we will not spend a great deal of time in talking about fatty degeneration of the heart, when you cannot tell what is the matter with the patient when he has it.

Now, the other kind is altogether different in its effects upon the heart, and altogether different in its pathological aspect. The heart muscle is a striped muscle. It has cross markings, lines in the direction of its leng h, and lines across, dividing those muscles, as the muscles of the

arm and leg, and all the voluntary muscles of the body are, into little checks. Well, these checks, when Quain's degeneration occurs, come to hold first a little oil globule. A muscular element seems to be removed from it. The place of the muscular element is taken by oil drops, minute, microscopic drops. I can show you a plate the next time, that will, perhaps, give you a better idea than any of my splendid drawings, but you may get some idea of it from this drawing. Well, then, this sort of heart has become useless. No, not quite, because this sort of degeneration is unequal in the walls of the cavities. It will be here marked, and at another place scarcely noticeable. The result of this production of oil within a muscle, covering the sarcolemma, is to change the color of the heart, and to change its consistency. Here, for example, are three specimens of this kind of degeneration. This one is not so very much softened. It seems to be small. The walls of the heart are thin, but the cavities are not dilated. The peculiar color that the oil gives to it is noticably yellow. Here is another which is soft and yellow, and the walls of the heart are a little thinned, but not reduced so much as that you would be able to recognize it during life. And here are several other specimens which you will examine with regard to color, etc.

In regard to the recognition of this form of disease, it is more nearly possible than to recognize an adipose deposit upon the exterior of the heart. For example, I was called to see a lady, not quite middle aged, in whom there was marked irregularity in the action of the heart. I measured its size; that was natural. She was of an age that would hardly admit of the supposition that she had bony degeneration of the heart structure. That belongs to advanced age. She was not more than thirty, or perhaps thirty-five. She could lie down flat in bed, that is to say, she could lie down on her back without any pillow or bolster, and felt better in that position than with her head raised. She was dizzy, and disposed to faint when she walked about, and particularly when she made any exertion. The peculiar irregularity—I say peculiar; I do not know that that is the proper name—the marked irregularity, the irregular irregularity in her heart fixed on my mind that there was some disease of it. In using that expression, irregular irregularity, I ought perhaps to define it. When a heart beats on for five, six, or seven minutes, and then drops a beat, that is an irregularity; but there is a certain degree of regularity in its recurrence. You may count a certain pulse, and find that the sixth is dropped through a whole minute. But when there comes a kind of irregularity, that you cannot describe, when the heart beats perhaps rapidly in this way and then holds up, beats slowly, and then directly begins with a sort of fluttering that is hardly describable in words, that is what I mean by irregular irregularity as contrasted with the regular recurrence of certain phenomena in the action of the heart. Well, this lady had that. The heart beat with an irregularity that is hard to describe. Now, it will be well for you to remember that that belongs to some particular disease of the heart; that that particular irregularity, that you cannot well describe, does not come of mere functional disturbance, but is always, as far as my memory goes, associated with a change of some kind in the structure of the heart or its valves. I said to the Doctor who called me in, "I am confident there is some disease of the heart here, but I cannot tell what it is." Had I known the fact that in this kind of degeneration it is not uncommon that patients can lie down with the head low in bed, and feel better than when the head is raised, I might perhaps have made a reasonable conjecture. But at that time I did not know it—thirty or forty years ago. This lady died, and we had a post-mortem examination, and the heart I think is one of these. I examined various portions of it under the microscope, and found the kind of degeneration that I have been trying to describe to you, more or less in all the parts of its walls. But it was very marked, more marked than anywhere else, in the fleshy columns, and this perhaps was one reason of the marked irregularity. They performed their office very imperfectly, and by sympathy disordered the heart.

This kind of degeneration is, again, of rather rare occurrence. It may occur at any age. It may occur upon hypertrophied and dilated hearts, and it may occur upon hearts that are perfectly normal in size and up to the time of its occurrence perform their function perfectly.

I do not know what causes this Quain's degeneration. It is something connected with the nutrition, the nerves of the organ. Persons who have it do not become œdematous, they do not become always very pale. This lady that I referred to was pale and icteric, but I did not refer the icteric element to the heart, unless perhaps the liver was deranged by imperfect circulation of blood through it.

As to the treatment of this particular form, if you make it out, there is but little. A rather extraordinary recommendation has been given,

however, by one physician of some authority, and that is to make the patient to run up-stairs. I think it would kill more than it would cure. The idea is to make the heart active, and to cause it to be nourished by healthy muscular tissue in that way. But my own opinion is that it cannot be done. The treatment that I should adopt, and have recommended in cases where this disease was suspected, is of an entirely different character. It is aimed at causing the absorption of the fatty matter, and reduction of the supply of fat in the body; for example, the patients, as in two or three other forms of disease that depend upon fatty disorders that I shall describe to you further on, are directed to take moderate exercise, to walk upon the level ground, or upon the floor of the house, and take, according to their strength, the exercise they can endure. The second element of the treatment is absence from all fatty food, including butter, milk, cream, fat of meats, and in a manner all fatty food. I sometimes allow them enough of milk to flavor their tea or coffee, but nothing beyond that. Only lean meats, and the vegetable foods that contain the least oily matter. Well, the grains; perhaps you ask whether they contain oily matter; yes, they contain oily matter. Wheat contains about three per cent.; Indian meal contains about ten per cent.—that is the reason it fattens the hogs so fast. Then I should prescribe food made from wheaten flour rather than from Indian meal. And next, and perhaps the most important element in it, is to administer the bicarbonate of soda, and to administer it to such a degree as it will be borne, and that fact to be judged of by a daily examination of the urine. In giving alkalies you are to bear in mind that some of them have the power of producing calculi in the kidneys or bladder, but there is no danger of their producing anything of this sort as long as the urine is in the slightest degree acid. Furnish your patient, then, with slips of litmus paper, to be kept in a convenient place, as in a box about two inches and a half long and an inch and a half wide, and let the patient take every morning, or every evening (better in the evening), one of these papers by one of its ends and dip the other in the water, and when it comes out, is it red, or is it purple? If it is purple the patient is taking too much soda; if it is in a very slight degree red, that is all right; if it is very red, he is not taking enough; give more. And in this way, from day to day, by applying the test, you may give what will be safely borne and what will produce most effect upon the fatty degeneration of any kind in the body of the patient. I do not know from experience that it will do any good in this kind of fatty degeneration; but it does so much good in other kinds of fatty degeneration that I deem it important that it be tried. Of course, the most nourishing food that the patient can take is to be preferred; beef and mutton, all lean, and not excluding chicken and fowls of various sorts. Any good wholesome meat food is better than vegetable food in this case; at the same time some vegetable food may be taken.

Communications.

A NEW MEDICAL SPECIALTY.

BY F. E. STEWART, PH.G., M.D.,
Of New York.

In the olden time the physician was his own pharmacist—that is, he was obliged to prepare and dispense his own medicine But the duty becoming too laborious, on account of the growth of science, it was entrusted to an assistant. The assistant chosen was the apothecary. Now, the business of the apothecary has been, from time immemorial, to sell drugs; and it was not until a more recent date that he was also entrusted with the new and responsible duty of assisting the doctor. It is now claimed by the medical profession that the apothecary is violating his trust; and that the violation consists in that he is doing other business beside assisting the physician. He is accused of selling drugs without an order from the doctor, and in the irregular forms of patent medicines, trade-mark pharmaceuticals, etc. he is blamed for prescribing over the counter, and for renewing prescriptions at the request of the public, to whom the law declares the prescription belongs. Is the apothecary at fault for this? Is he not a merchant in drugs, as in the olden time? If a merchant only, he owes no allegiance, and is not amenable, to the medical profession, or any other sect or profession. His relations are entirely with the general public. What the public demands he must do. If the public demand of him drugs, fancy goods, soda water, patent medicines, a few groceries, whisky and segars, should he be blamed for selling them? If the people also ask him to renew their prescriptions, they do not belong to the doctor, and has he any right in the matter? Surely the people do not recognize that right, if it exists. These are vital questions, and until they can be satisfactorily answered it is easy to see the position which the apothecary must hold in relation to the medical profession.

The next question is, what shall the doctor do,

under the circumstances? Discharge his assistant and employ a new one, or retain the old? But this question is being answered for the physician by the evolution of events. Pharmacy has become too burdensome to the apothecary, as to the physician of old, and he has delegated it to the manufacturing pharmacist. The enormous growth of the business of the manufacturers during the past decade proves that this transition is now going on, and the correctness of this statement. It is important, then, that the profession should know more about the manufacturers, their polity, and their relations to the medical profession. Are they merchants, too, doing business with the general public? If so they owe no greater allegiance to the medical profession than the apothecary. If, on the contrary, manufacturing pharmacists claim to be a branch of scientific medicine, they should conform to the rules which govern a scientific profession.

I do not know what policy the manufacturers have adopted in this matter, but judging from their declaration of love for science, and affectionate regard for the physician, the profession are led to believe that they are what they certainly attempt to convey by their assertion, scientific pharmacists. Arguing, then, that this is the fact, manufacturers owe their allegiance to the medical profession, and have no right to interfere with the physician's prerogatives. The medical profession, however, will have to arraign certain of these manufacturing houses on the charge of not only interfering with the physician's prerogative, but also of attempting to usurp his province of treating the sick. But first, why have they not a right to treat the sick? The answer is simple. Because they are not physicians, either by education or training. If physicians, would they not have the right to practice medicine and pharmacy both? I answer, yes, under the same rules and regulations which govern the medical profession, but not otherwise. But they are charged with practicing medicine without a medical education; and also of using unfair means of competing with the doctor. Counsel for the profession will support this charge by the plea that certain manufacturing pharmacists are preparing for and advertising ready-made prescriptions to the public; that they send out medicines under ingenious names, protected by trade-marks and patents, and then solicit the doctor to prescribe the same; but that these trade-mark pharmaceuticals are accompanied with labels, and circulars, carefully worded to catch the public eye; that they are advertised in the secular and religious press; and as if to exasperate the profession still further, it is claimed that this whole system of abuse is cordially sanctioned by the medical profession. This attempt to obtain the public patronage belonging to the medical profession is too apparent for controversy. That it is the exclusive prerogative of the physician to treat the sick some may be disposed to deny. They may claim that prescribing druggists, quacks, old women, and patent medicine men share equal privilege with an educated profession; but no fair mind can excuse this contemptible hypocrisy, which, under the guise of friendship, seeks to undermine the medical profession.

What will become of the physician if this condition of affairs is allowed to go on? It is a rivalry of organized executive ability against an unorganized, impoverished profession. Upon one side is all the machinery of trade, facilities for marketing goods and creating a demand for them by advertising; on the other a profession who have neither the time nor opportunity for trade. Is not the answer apparent? When the medical profession, forced into adopting trade to gain a livelihood, are prevented from devoting their time to the investigation of disease and means of cure, the wheels of progress will be clogged, and the advance of science greatly hindered thereby.

What shall the physician do, then, for his own protection? Beset with powerful foes, behind and before, there seems to be but a poor showing for him. To answer this question it is necessary to look at this subject from a new and entirely different standpoint. It is the relation between trade and science, which, entering into this question, greatly complicates the matter.

A clear line of demarkation should be drawn between trade and science. They are exactly opposite in their tendencies, and it is the attempt that is being made to mix up trade with science that is causing all, or at least a great deal, of the trouble and feeling between the medical profession and the drug trade. For the sake of illustration, trade can be represented by protection, science by free-trade. Science professes to exhibit what is actually known or may be learned by exact observation, precise definition, fixed terminology, classified arrangement and rational explanation. It is impossible to satisfy the demands of science by any system of protection, as science demands the publication of the whole truth, and its classification into the forms of science, for the benefit of the world.

The whole tendency of trade, however, is a selfish one. Trade seeks to protect her own interest without regard to others. While science

is laboriously delving in the mine of knowledge, to dig out the ore, trade coins it into money. But greedy trade, instead of coöperating with science, for mutual benefit, seeks not only to monopolize all the money, but all the knowledge as well, forgetting her debt to science.

Take this illustration and apply it to the scheme already referred to, and the tendency of trade will become apparent. As before shown, it kills the miner; but in addition to this it locks up the mine. Let me illustrate! What would have become of science if heat, light, electricity and all other forces had been patented when first discovered? Would not trade have locked up these forces and prevented their investigation? The patent law was designed for the protection of science in this matter, by offering the inventor seventeen years' control of his invention, in exchange for its publication. The patent law was not intended to lock up forces from investigation, but, on the contrary, to encourage the investigation of forces. While it does not patent electricity, it protects the inventor of a dynamo-electric machine. Medicine is a curative force, and should not be patented, any more than heat, light, or other forces. By patenting medicine scientific progress is hindered, trade is injured, and the interests of suffering humanity are sacrificed. To this may be answered, that the patent is granted upon certain compounds only, not upon the drug itself. I answer, yes, but the compound becomes, to all intents and purposes, the same as a new drug, and the control thus gained permits unprincipled manufacturers to create a demand far above real worth, by advertising cures only. Honorable trade is thus thrown into disrepute. Legitimate competition is the cure for this.

Now, I claim that pharmacy is a science, or rather, a branch of a science, and should be so regarded. It should be separated from trade, otherwise it will be eventually locked up by trade, and scientific progress rendered well nigh impossible. And this is very important to the medical profession, as pharmacy is a branch of the science of medicine. Pharmacy, according to Dunglison, "is the art which teaches the knowledge, choice, preservation, preparation and combination of medicines." The practice of this art might have been at one time the province of the apothecary, but at the present time it is not carried on exclusively by any one class of individuals. The several functions which together constitute the practice of pharmacy are divided up among the drug brokers, wholesale druggists, manufacturing pharmacists and apothecaries. The drug brokers and the wholesale druggists select the drug and carry it in stock, the manufacturers make it up into pharmaceutical preparations, and the apothecaries dispense it. Some of the manufacturers are combining in their business all of these functions, and they should be looked upon as the nearest approach to the ideal. These houses select their own drugs, often import them, and sometimes even send accredited agents to the source of supply, to gather them, under the most favorable conditions of climate, soil and season. Manufactured into the regular forms of the pharmacopœia, they are dispensed to the apothecary, and by him, in turn, to the patient, upon the prescription of the doctor.

Manufacturers, however, are not practicing pharmacy as a profession, but as a trade. By this I mean that these houses are running their business upon a trade basis, not a scientific basis. If they were on a scientific basis, they would publish all their different methods of manipulation for the benefit of science. They would have no trade secrets whatever. They would tell just how they sugar coated pills, the best way to gelatin coat pills, and every other little manipulation of the kind. They would not only furnish this information to those who might ask it, but they would take particular pains that it should become items of scientific information, and the public property of the profession which they are supposed to represent. Otherwise they cannot be regarded as scientific pharmacists.

This being necessary to constitute a scientist, have we any scientific pharmacists? I claim not, at least as a class. The business of the apothecary cannot stand this test, though there are apothecaries that take this stand. The business of the manufacturers cannot stand this test, though there may be an exception. One manufacturer with whom I talked said that though he was willing to publish all formulæ, and as a rule did so, yet he did most assuredly object to giving every lazy competitor the benefit of his enterprise and skill.

But pharmacy as a business being on a trade basis, and therefore subject to trade tendencies, what is to become of pharmacy as a science? As already stated, pharmacy is a branch of the science of medicine. It is necessary to be learned in all the branches of a science to be thoroughly versed in any one branch of that science. A pharmacist must be, therefore, a physician. To be scientific he must publish the results of his investigations for the benefit of his profession. But such a publication is not always compatible

with trade. A scientific pharmacist should not, therefore, be a tradesman. There is a demand, then, for scientific physicians, educated in pharmacy, to take up pharmacy as a science. Is there not room here for a new medical specialty? The physician did not give up his right to make pharmacy a study, by employing an assistant. He cannot expect his assistant, uneducated in medicine, to be proficient in the investigation of drugs. He must possess an accurate knowledge of every property which they possess, physical, chemical, therapeutical, physiological and pharmaceutical, to justify him in any original investigation of his own.

The province of this specialty should be to investigate drugs, with the view of classifying them for the benefit of science. Every new drug brought to the notice of the physician by trade should be thoroughly tested, and the results of these tests furnished to the physician. Of course, patients should not be experimented upon with unknown drugs, without sufficient reason to justify their use; but valuable drugs have come to us from unscientific sources. Because a drug is used by a quack, an Indian medicine man, or an old woman is no proof that it is devoid of virtue; and when it is the universal belief of all old women that certain herbs possess certain virtues, we are just as much justified in trying them, to see if this belief is founded on fact, as were our grandfathers, who collected the best of them to make a pharmacopœia.

Hospital physicians, especially, should take up this line of work, for in the hospitals there is a better chance to observe cases. Not one hospital, only, but many hospitals, should investigate the same drug, for in that way comparative results can be ascertained, and the true worth of the drug made known.

Finally, let trade and science unite in this commendable work, for it is for mutual benefit. The knowledge of new drugs will be a benefit to science, for by it the physician is better armed and equipped to combat disease, and now and then a valuable gem is picked up, which otherwise would have been lost to the world. A publication of the truth regarding new drugs is beneficial to trade, as it increases the demand for good drugs, which trade only can supply.

Says Aaron to Moses:
"I've got trichinosis."
Says Moses to Aaron:
"'T is because you pork fare on."

ON THE USE OF THE OBSTETRICAL FORCEPS.

BY T. C. WALLACE, M.D.,

Of Cambridge, N. Y.

A paper read before The Union Medical Association, at Eagle Bridge, N. Y.

Gentlemen—To any one who has been an observant reader of medical literature, it must be evident that, especially for the past few years, the aim of the profession, and particularly of its leading members and teachers, has been to develop something novel. Disdaining the beaten track of our fathers, the striving has been for new remedies, different instruments, and novel appliances, and the claim invariably made for every new thing thus developed is, that it is a great improvement. Is this claim always justified?

For the past twenty years the medical press has teemed with glowing accounts of new remedies, whose virtues have been extolled until it would seem that a certain antidote for every human ailment has been found, and that a physician who, with such certain remedies at his command, allows any one to be sick longer than a few days must be "behind the times," and that the physician who suffers a patient to die must necessarily be himself to blame. Now (without denying that progress has been made), I ask, of these much vaunted remedies, how many are today in use? How many have demonstrated a practical value? How many more reliable remedies have we at our command than had our immediate predecessors?

In no department of medicine has this tendency been more manifest than in Obstetrics and Gynæcology. No one can claim to have achieved anything in this department until he has invented a new speculum, or a new pessary, or given his name to a new obstetrical forceps. As proof of this last remark, I find enumerated in the catalogue of one surgical instrument maker 66 different specula vaginæ; 84 different pessaries, and 51 different obstetrical forceps; and this catalogue does not enumerate all. Of the great majority of these last-named instruments it would, indeed, require an expert to detect any practical difference whatever.

Now, I am sufficiently conservative to avow my belief that there is virtue yet remaining in old methods, in time-honored appliances; that every new remedy is not a specific, nor every new instrument necessarily an improvement; and that often we may best serve our own interests, and most promote the welfare of our patients, by becoming familiar with the administration of long-

established remedies, and by perfecting ourselves in the use of the instruments of our fathers.

I know no more pertinent application of this belief, than the consideration of the use of the obstetrical forceps. The longer I practice medicine the more firmly established is my opinion of its inestimable value, and the oftener I resort to its use. Yet it is true (and to me it seems a lamentable truth), that very many of the profession regard its use, if not exactly with disfavor, or as something to be resorted to only in extreme cases, or when nature unaided is unable to accomplish her work. Many a practitioner skilled and ready in every other resource of our art is afraid to use the obstetrical forceps, and there is no operative procedure that has such terror to the beginner. To me, who consider its use easier than passing the catheter, and as devoid of danger as the use of the hypodermic syringe, this seems strange.

A member of this Society and an excellent practitioner recently remarked, "He thought it better for a woman to suffer, suffer severely, suffer long, and do well afterward, rather than be subjected to any operative procedure and incur perhaps lasting injury thereby." This proposition is eminently true, but is it not equally true that it is better to relieve the woman of this severe and protracted suffering by the use of the forceps, with the proviso that absolutely no injury shall be inflicted upon her or her child?

Firm believer as I am in its beneficent action, thinking, as I do, that we have at our command no instrument which is so eminently efficient in saving life and in abridging the duration of human suffering, an ardent advocate for its more frequent use, and my sole object in writing this paper being to induce my professional brethren to resort to it more freely, I am inclined to search for the cause of this general distrust.

First impressions are truly said to be lasting, and to the impressions we received while students, from our preceptors, our text books, and at our colleges, must much of this distrust be attributed. First we are met by that solid glittering *chunk* of obstetrical wisdom, "A meddlesome midwifery is bad." This is brought forward as a perfectly unanswerable argument. What is meddlesome midwifery? Webster defines the verb meddle, "to take part in a thing with which we should have nothing to do." Now labor is a physiological process which is apt to assume a pathological character. So long as it acts physiologically, we have no more business to interfere with the uterus in the discharge of its contents than we have to interfere with the rectum or bladder when they are acting normally. To do so would be to meddle, "to take part in a thing with which we should have nothing to do."

Many things commonly done in the lying-in room are "meddlesome." It is "meddlesome" to require the woman to assume a particular position, especially if that position is irksome to her. It is "meddlesome" to urge upon her quantities of warm drinks. It is "meddlesome" to introduce a finger into the anus and endeavor to pull down the head. It is "meddlesome" to tell her when to hold her breath, and when to bear down. Nature will teach her that effectually.

These and many other things often done are "meddlesome." But it is *not meddlesome* to assist nature when she is unable properly to complete her work; nor is it "meddlesome" to put her right when she is wrong. Neither is it "meddlesome" to put a speedy end to a case of tedious labor with the forceps; or, if this must be classed in your minds as "meddlesome midwifery," I respectfully submit it is *not* bad."

Similar to this is the saying so often heard, and which with many rises to the dignity of an aphorism, "Let nature take its course." The doctor is called at night to a case of labor; after examining the patient and pronouncing "everything all right," he requests to be shown a bedroom, and is soon wrapped in slumber. By and by he is aroused and informed his patient is very sick. He finds her in strong labor, perfectly agonized by the violence of the pains, and she earnestly entreats him for relief. "Can't you do something for me, Doctor?" His reply is, "let nature take its course."

How comforting, how eminently satisfactory such a reply must be to a patient so situated! What an exalted opinion she must form of the resources of the medical profession! Nature takes its course. The doctor returns to his couch and to his slumber, the woman passes hours of unspeakable agony. What are the teachings of many of our text books on this subject? Meigs says: "either the pains must have proved insufficient for their office or else the urgent demand for delivery, arising from hemorrhage, convulsions or other states, must establish the indication for their use. We should be inexcusable if we used them when the pains are still of vast force and fail of success on account of a preternatural resistance." Churchill: "that they are to be used in no case until we are perfectly satisfied that the obstacle cannot be overcome by the natural powers with safety to the mother and the child." Denman: "that the

head must rest immovable upon the perineum four hours before the forceps be resorted to." Ramsbotham: "before the forceps can be applied, the os uteri must be entirely dilated, and the head must come down into the pelvis sufficiently low to enable us to feel one or both ears distinctly. It is necessary to touch one or both ears, because they become the guide for the proper application of the forceps. Again, if no progress has been made for a number of hours, and especially if impaction has existed for six hours, then, provided an ear can be felt, and the parts are not so rigid as to endanger laceration, we are justified in using the forceps." Merriman: "that the forceps should never be applied until the ear has been in reach of the operator's finger for at least six hours."

Some authors have gone so far as to demand that there should be a cessation of pains, and that the patient should become restless, hot, thirsty, with a rapid pulse and other indications of febrile excitement, before any instrumental assistance be rendered. According to many authors the use of this instrument is fraught with great danger to mother and child. Churchill says: "the vaginal parietes may be lacerated, the blades may be pushed through the vaginal or uterine walls, the soft parts may be torn in the extraction, the os uteri may be included between the extremity of the blade and the head, the child's scalp may be bruised, or torn, or an ear cut off." Cazeaux speaks of "lesion of the cervix and perforation of the vagina; of the sudden emptying of the womb giving rise to inertia and hemorrhage." Elliott, in addition to danger to the mother, mentions, "fracture of the child's skull, peeling off the scalp, and even gouging out the eyes." Blundell: "in violent hands the large forceps is a tremendous instrument; force kills the child, bruises the soft parts; occasions mortification, breaks open the neck of the bladder, etc." So deeply impressed is he with the danger attending its use, that he counsels us frequently to count the patient's pulse, to see that she is not dying. Bedford, however, caps the climax. Among other horrors he mentions "fractured pelvic bones, separation of the symphysis, with laceration of the ligaments, rupture of the uterus and vagina, thrombus of the vulva, and pelvic abscesses." He gives in detail a case of "complete occlusion of the meatus urinarius, with adhesion of the walls of the upper fourth of the vagina, together with a vesico-vaginal fistula," all caused by a forceps delivery.

We are also led to think the application and use of the instrument an exceedingly difficult matter, and sometimes requiring unusual skill. All authors yet named direct that the blades must invariably be applied to the head in its bi-parietal diameter. No matter what the position of the head may be, "it is the position of the head which must determine the position of the blades." Hence is placed upon the operator the imperative necessity of ascertaining the exact position of the head. This is not always easy, even to the experienced practitioner. Not seldom it is difficult and uncertain, and sometimes it is impossible.

To the beginner, of course, the difficulties are vastly greater; not certain that he is correct as to the position, he is not sure his blades are rightly placed. The rules of application, of course, vary according to the position, each change of position requiring a corresponding change for the instrument. Bedford has four different rules for its introduction at the upper strait, and four at the lower. Dewees makes seven primary positions of the vertex, and has a different rule for each of these, and still others for rarer positions. Cazeaux has different directions for each of eight vertex positions: and so on with other authors. No man can possibly remember so many different rules, and the practitioner becomes hopelessly befogged. Having been thus taught that grave emergencies alone justify a resort to the forceps, that its use is often productive of fearful injury, and that its application is a matter of great difficulty, is it strange the physician, and especially the young practitioner, has a distrust of this instrument; that he should delay its application so long as he possibly can? Now, I claim (and I hope to substantiate the validity of this claim), that these teachings are wrong, all wrong, in every respect. That it is not reasonable, it is not right, to wait for any such emergencies before using our forceps; that by such delay we do gross injustice, not only to ourselves, but (what is far more important), to our suffering patients; that the injuries mentioned are never caused by the *use*, seldom even by the *abuse*, of the forceps, but are almost always the result of the delay recommended; that the rules given for its use are erroneous, unreasonable, and themselves the frequent cause of evil consequences. It may seem arrogant in me thus to speak. I may be deemed lacking in the respect and reverence due to these "eminent authorities," to thus question their teachings; but I claim that respecting matters of fact, facts of practical demonstration, and that come under observation as often as these, an experience of thirty years entitles me to form

an opinion for myself, and to conduct my practice conformably to that opinion.

It has been well said, "before a man writes a book he is just a common doctor, like the rest of us; but so soon as he deliberately writes his opinions in a book he becomes at once an *authority*, and his sayings are then, to many, as the voice of inspiration." Are our authorities always correct in their statements? Are they uniform in their teachings? Many pass their pupilage without seeing a case of midwifery. Let such a one be called to attend his first case of labor, what position will he naturally expect his patient to assume? He has read in his text-books, heard from his professors, "that it is the universal custom in this country and England for the woman to lie upon her left side, with her knees drawn up." Meigs, indeed, states "that the influence of this custom is so great, that a proposition to turn upon the back is frequently received with astonishment and aversion, as, at the least, indelicate!" Does this statement, uniformly made by all our authorities, accord with your experience? I ask you, gentlemen, do your patients usually assume this position? How many women have you ever delivered while lying upon their left side? Here is a statement in which all our authorities agree, and I leave you to answer as to its correctness.

To be Continued.

Copaiva in Sciatica.

Dr. H. C. Marsh writes to the London *Med. Times and Gazette*, of copaiva:—

I wish to speak of this drug as wonderfully efficacious in sciatica. The treatment of sciatica seems to be a little indefinite. I fancy we all meet with very troublesome instances in which we administer a variety of drugs with a perseverance that deserves, but does not always command, success. (After describing a most obstinate case he stated) at last I prescribed

℞.	Bals. copaib.,	ʒiv
	Tr. lavand.,	ʒiv
	Tr. hyos.,	ʒiij
	Pot. bicarb.,	ʒj
	Mucilag.,	ʒj
	Aquæ,	ʒvj. M.

A tablespoonful every four hours.

On the 26th the pain was almost gone, and she was radiant with smiles; but she rebuked me, with some show of reason, for not having given her this marvelous medicine at the outset.

I naturally looked upon this recovery as a mere coincidence—a happy chance; and the affair passed from my mind.

Nine months afterwards, on December 31, 1878, I was called in the night to see Mrs. J., who had been in bed for a week, with sciatica of left leg. The pain was so severe that I administered hypodermic morphia at once. She was a tall, thin, temperate—indeed, rather abstemious—woman, with perhaps a tendency to neuralgia. Her family are a little consumptive. I could not suspect her of the shadow of an intrigue. She had a grown-up family and a model husband; she was over fifty years of age. Her secretions were natural, and she seemed free from disease. I gave her the muriate of ammonia. On January 2 she was no better, and I prescribed full doses of bromide with colchicum, but refused her entreaty to repeat the morphia. No better on the 4th; so she then had belladonna and phosphorus. On the 7th, as the pain was growing more severe, she took syrup of the iodide of iron with phosphorus; and had a liniment of belladonna, aconite and veratria. On the 12th her sufferings were worse than ever. All the night through she had lifted up her voice and wept. The relatives gathered round me with upbraiding faces. One may manage a patient, even if she refuses to improve; but the patient's friends have one at a disadvantage. I was obliged to see her twice during the day, and each time considered it prudent to administer hypodermic morphia. On the 13th she was just the same, when—happy thought!—I suddenly remembered the former case, and prescribed the copaiva mixture. The next day the pain was nearly gone, and on the 20th she was quite well.

This time I did not forget; but have used the remedy lately in many cases, both male and female, with like success. I do not *begin* with the drug; thinking it better first to empty the bowels, and to relieve any gouty, rheumatic, or anæmic state that may happen to exist; but fall back upon it if the pain continues unabated.

In explanation of this therapeusis I have very little to say. Ricord remarked upon the action of copaiva on the nervous system, and noticed a case in which it produced temporary hemiplegia; and Maestri records an instance in which large doses of the balsam occasioned partial paralysis of the facial muscles.

For my own part, I am inclined to associate the remedial property just indicated with the drug's well-known power of producing diuresis in certain forms of hepatic dropsy. It seems to have an action on the liver; it certainly stimulates the kidneys; and it exercises some influence on the nervous system.

Slight Results from Serious Brain Injury.

In the *Canada Journal of Medical Science*, March, 1881, Dr. Daniel Clark, of Toronto, gives this curious case:—

About seventeen years ago I was called to visit a boy, aged thirteen, who had been kicked by a horse. A section of the skull was crushed in on the right side, near the median line, in the upper part of the frontal and parietal bones. One of the nine pieces fractured and detached from the surrounding bone had been driven into the substance of the brain, over an inch, in a perpendicular direction. The membranes were lacerated very much, and brain substance, within a few grains of an ounce in weight, protruded through the wound, much broken up, some of it hanging down upon his cheek. At the time I first saw him he was comatose. I extracted the bones, cut away the ragged edges of the membranes and the lacerated brain substance. Consciousness returned immediately. His temperature remained normal; his pulse did not rise at any time above ninety-six. He did not lose a night's sleep nor a meal after the evening of the accident. No febrile symptoms intervened. There was no paralysis, nor perversion of any of the organs of special sense. There was no difficulty in speaking. A large cavity remained. He afterward went to school to the same mistress as before, and she informed me that with the exception of a certain irritability of temper when thwarted (which he did not possess before), he was as intelligent as ever, and could learn his lessons with the usual aptitude. This was especially noticeable in mental arithmetical exercises. He was under my observation for several years after the accident. After he was aroused from his comatose condition, consequent on compression, his special senses were unimpaired, his locomotion and grasping power normal, and his bodily health good in every particular.

Salicin in Acute Rheumatism.

Prof. M. Charteris, M.D., of Glasgow University, writes to the *British Medical Journal*:—

Experimentally, I tried, four years ago, in two cases of equal gravity, salicylate of soda and salicin; and I found that the former produced decidedly alarming and toxic results, while the latter excited its harmless and beneficial influence. I was so much impressed at the time with what I witnessed, that I resolved never to give the artificial compound again in the disease, but to trust to the natural product, and in doing so I have been led to formulate the following conclusions:—

1. In uncomplicated cardiac cases, salicin in doses of twenty-five grains, dissolved in warm water or milk, will lower the temperature in forty-eight hours.

2. When this has been accomplished, diminish the frequency of the repetition of the dose mentioned to every six hours; and finally, after two days, stop it altogether, as its further continuance is useless and depressing, and retards convalescence.

3. If the temperature be not lowered in the time mentioned, in all probability the heart is affected; and if such should be the case, the medicine should be countermanded, for it will then in no way diminish the fever. The cardiac complication may not be detected by auscultation at the time; but it will invariably be found that a cardiac murmur exists at the natural termination of the disease. For this cardiac complication I apply a large blister over the region of the heart, and do not allow it to heal quickly.

4. Previously to employing salicin, I test the urine for albumen; and if this be detected, and if there be a suspicion of old-standing kidney disease, as revealed by the history of the patient, it is probable that the drug may not be properly eliminated from the system. That it is so, can be readily seen by testing the urine at intervals by tincture of perchloride of iron, when a purple color will be observed, owing to the action of the iron transformed in the system into salicylic acid. Should this reaction not be seen, it is well to discontinue the use of salicin.

5. Finally, I may state that I have never in any case found salicin to cause thirst or delirium. These phenomena may be attributed to impurities in the artificial compound—probably to carbolic acid. Salicin seems to me to have some special action in rheumatism, for it will be found not to lower the temperature in other affections where this is high. Thus, in a case of advanced phthisis, it is inert in large doses; while quinine, in similar circumstances, exerts its usual antipyretic virtues, when given at a different time to the same patient.

In a recent visit I made to some of the chief Continental hospitals, I found that the pure salicin was now alone employed, and, I may add, implicitly believed in, for acute rheumatism.

Spinal Irritation without Deformity Treated by Suspension, and the use of Plaster-of-Paris Bandage.

The following valuable paper, by A. A. Henderson, M.D., of Ottawa, appears in the *Canada Lancet*, March 11: I wish briefly to state to the profession the result of treatment of several severe cases of spinal irritation without deformity, cured by suspension and the application of plaster-of-Paris, after a thorough but unsuccessful trial had been made of the means usually adopted in the treatment of that severe complaint. I applied it for the first time, in this disease, on the 11th of March, 1878. After having for twenty-two months faithfully attended my patient, and during that period having repeatedly had consultation with professional friends, and used thoroughly every remedy which they or I could suggest, I applied a jacket, which gave immediate relief. Suspension was not only perfectly painless, but in addition, the pain caused by the disease ceased the instant the patient was raised by the suspender. As a result of this and subsequent cases, I feel satisfied that in suspension and plaster-of-Paris we have a means as certain to cure in spinal irritation without deformity, as in spinal curvature, and giving as perfect and immediate relief from pain. I have not used this treatment in mild cases, for they as a rule yield readily to

more convenient means, but whenever the case shows obstinacy I now advise suspension and a plaster jacket, with perfect confidence as to the result. I give the history of three of the most interesting of the cases I have treated in this manner. (We give the second only.)

Case 2.—On May 10th, 1878, I was requested to visit Mrs. F. She told me that her health had been poor for several years, and for nearly four months she had been confined to her house, with symptoms which I found indicated spinal irritation of the dorsal region. No muscular spasms existed, and no deformity. I suspended her and applied the jacket in the usual manner. She stood the operation well, and was pleased with the change in her feelings. I ordered her to take abundance of fresh air and no medicine. Her health improved rapidly. I applied in all four jackets. On October 15th, 1879, I removed her last jacket, she being perfectly well.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Wm. Dickinson, of St. Louis, sends a reprint (from the *Alienist and Neurologist*), describing the mechanism of hemiopia, on the theory of total decussation of the optic nerve fibres in the tract at the chiasm. He formulates what he attempts to prove in the following four propositions:—

1st. Diseases involving the optic *tract* of *one* side will produce total blindness of the eye on the opposite side; and not bilateral hemiopia.

2d. Diseases affecting either lateral angle of the chiasma, involving both the optic nerve fibres entering and also those leaving it, will produce bilateral hemiopia; and not *nasal* hemiopia in *one* eye.

3d. Diseases affecting the posterior angle, in the median line, involving the optic nerve fibres of *both* tracts that enter the chiasma, will affect the outer half of each retina and produce *nasal* hemiopia; a form utterly inexplicable on the theory of partial decussation, and

4th. Disease in front of the commissure will affect the inner halves of each retina, and produce temporal hemiopia; the phenomena of which are alike explicable on either theory.

——The Report of the Indiana State Health Commission for 1880, Dr. Thad. M. Stevens, Secretary, is a pamphlet of fifty-one pages. Indiana has not got so far as the creation of a Board of Health, like Pennsylvania and some other States; it is not yet sufficiently civilized for that; but it has this "Health Commission," a body without any authority and with very little money. The Commission does all that it can do, which is not much. It advocates strongly a State Board of Health and Local Boards. The Secretary appeals urgently for this, as he says (p. 5):—

The entire profession of the State, without regard to isms, pathies or divisions, should be bound together in the work connected with vital and sanitary science. This can only be done by a law of the State, and such law must have bodies organized to act in the several precincts of the State, and not depend upon one to collect statistics, or complete investigation.

The present pamphlet contains a number of papers of unequal merit, on such subjects as "The Prevention of Disease," "Healthful Homes, or, the Hygiene of the Household," "Malaria," "Scarlet Fever," "Diphtheria," "Human Longevity," etc. The prevalence and the injury of concealing and lying about the prevalence of contagious diseases, are forcibly commented on by Dr. G. W. Burton, in the paper on Scarlet Fever. He writes:—

In many towns they have denied the existence of the disease when deaths were occurring daily from it. I am thoroughly convinced of the fact that if local boards of health, school trustees, and those in authority in the towns and cities of the State had done their whole duty by isolating the first cases, more than 80 per cent. of the children of the State now sleeping in the church yards would be living.

Such concealment is at all times and everywhere fraught, in the long run, with bad results.

——We have received the "Publishers' Register, of books sent for notice to leading Medical Journals," ruled for titles of books sent, and printed address of the Papers and Periodicals sent to. It is also well adapted as an Exchange List and Subscription Book, as a free list of all Medical Journals published in the United States, printed on gummed and perforated paper, accompanies each copy. Prices: 12 cap pages $1.00; 24 cap pages $1.50; 48 cap pages $2.00. Gummed and Perforated address of Publishers and Medical Journals, 50 cents, per 100 names. Howard Challen, Publisher, Philadelphia. Also for sale at this office.

BOOK NOTICES.

Transactions of the American Ophthalmological Society, Sixteenth Annual Meeting, Newport, 1880. Published by the Society in New York, and can be procured of the Secretary at No. 12 West 35th Street.

This number of the Transactions contains 174 pages, with twenty-three wood cuts, one phototype, and an interesting photograph of the fovea centralis of the retina, taken from a microscopical section. It is almost normal, except the plica centralis is absent, and this was probably owing, as stated by Dr. O. F. Wadsworth, in part, to the vitreous being so albuminous as to be solidified

by the preserving fluid used, namely, Müller's fluid, and later transferred to alcohol. Nine pages are consumed in the minutes, followed by thirty-four articles. Our space will not permit of an extended review of all the articles, but we shall notice those that are new or of importance to the active and well cultivated physician. The first important paper is Sympathetic Inflammation of the Eye following operations for Cataract, by Dr. David Webster. This is a rare affection, and it is reported by Dr. Derby, that in two hundred and eighty-seven cases of V. Graefe's operation he had seen no instance of sympathetic inflammation; yet every surgeon who operates on many or few cases of cataract will meet with such results. Three cases have come under Dr. Webster's own observation, in which the vision of both eyes was totally lost, and several others in which sympathetic inflammation of various kinds occurred, but were successfully combated by treatment. This treatment in Case v was as follows: "Leeches were applied to the temple, and iced cloths were assiduously applied to the eyes, and a four grain solution of sulphate of atropia was dropped into the eye six times in an hour, morning, noon and night. An ointment of belladonna and mercury was rubbed upon the brow and forehead. In most of the successful cases the pupil was drawn up and filled with a thick membrane, for which Iridotomy had to be performed. In the discussion which followed this paper, two important opinions were given, the first by Dr. E. Williams, of Cincinnati, Ohio, "That he had made it a rule for many years to refuse to operate upon one eye of a cataractous patient, so long as useful sight of the other remained. Particularly had he been careful to refuse to operate upon traumatic cataracts where the other eye was in good condition. He thought these cases were peculiarly liable to sympathetic trouble."

Dr. H. Knapp, of New York, did not think the advice just given should be an absolute rule of conduct. We know that in cataract of advanced years both eyes would always be affected, and it might be that when the second eye became useless the chance for a good result from the operation upon the first eye was much lessened. The longer the cataract existed beyond the period of maturity, the worse the prognosis. Cases of sympathetic ophthalmia after cataract operations were rare. He would, therefore, in a general way, formulate the indication for any extraction as follows: "Perform the operation when it offers the greatest chance of success." External circumstances may render it opportune to operate before or after that period; but, if we want to do the greatest good to the greatest number of our patients, this rule will stand criticism. By waiting, for instance, five years, until the cataract of the other eye has become blind, the cataract in the first may have become hypermature, degenerated, and complicated. Its removal then was dangerous for both eyes, whereas, at the period of maturity the operation would have been easier and a great deal safer."

The second article is a "Contribution to the Pathology and Treatment of Vascular Tumors of the Eyelids, by Dr. C. S. Bull, of New York. In the pathology or treatment, there is nothing new—he follows the ordinary plan of excision by the knife, preventing dangers from hemorrhage by the use of the lid-clamp forceps. A most important point is insisted upon by Dr. Knapp, that is, the removal of these tumors as soon as they are brought to the notice of the surgeon.

Article 3d, is a case of "Ectropion, treated sucessfully by Wolfe's method," namely, by the Transported pieces of Skin. The case which is reported by Dr. Arthur Mathewson, shows, by two well executed woodcuts, the great advantages of pieces of skin, of good size, transported for relief of the deformity of ectropion.

Article 4th, is another case of "Ectropion treated by Transplantation of Skin" from the arm of the patient, and the following are the Doctor's conclusions; comparing this single observation with the experience of the writers before mentioned, I should infer it were advisable—

"As to the surface of the wound:—

1. That it be clean, and free from adipose tissue.
2. That its base be even.
3. That there be little or no hemorrhage at the moment of transplantation.

Then, as to the flap:—

1. That it be at least one-third larger than the wound.
2. That its inner surface be clean and free from fat.
3. That it be subjected to no undue violence.
4. That it be secured in its new position without delay.

Finally, as to adapting the parts to each other:—

1. That the edges should fit evenly.
2. That they should be secured firmly.
3. That the parts should be kept warm and dry for at least twenty-four hours.

The advantages of this method are so evident as to require but few words of explanation:—

1. A second scar is not produced in the attempt to rectify the deformity, as by the Indian operation.
2. There is no pain caused by keeping the arm immovably fixed, as by the Italian operation.
3. The edges of the transplanted flap can be adjusted with the greatest nicety, which is not the case with either of these methods.

4. If the attempt should prove a complete failure, as a result of any accident, the deformity would remain virtually as at first.

In general, therefore, we have by it much to gain, and comparatively little to lose."

Article 5th, is an elaborate and carefully prepared paper on "Intraocular Lipæmia," by Dr. Albert G. Heyl, of Philadelphia; and 6th and 7th, "Tabular Report of Compound and Mixed Cases of Astigmatism," by Dr. W. S. Little. The Doctor also reports a case of "Traumatic Paralysis of the Superior Oblique Muscle," which is interesting, from the rarity of the muscle being affected. The improvement was chiefly due to the use of electricity. The Doctor also reported a case of Partial Paralysis of the Inferior Oblique treated by prisms. In two cases we have seen admirable results from a careful operation.

Cases seven and eight are reported by Dr. Henry D. Noyes, of New York. "Laceration of the Eyelids. Glioma of both Eyes, Removal, Recurrence, Death and Autopsy."

Report nine, is one of "Keratitis from Malarial Fever;" by Dr. Chas. J. Kipp, of Newark, N. J. As this is rather a rare affection to us, we give in full the details of symptoms and treatment.

"If the eye is examined shortly after the first symptoms of irritation are noticed by the patient, one or two or more slightly raised, irregular, opaque lines of varying length will be found on different parts of the surface of the cornea. At the same time some circumcorneal injection will be present. On the following day these opaque lines have increased somewhat in length, while at the same time the middle portion of the opacity has been transformed into a shallow ulcer. Under favorable circumstances no further increase in size takes place, the remaining opaque epithelium is thrown off, and reparation begins, to be completed only after several weeks. But not unfrequently the ulcer continues for days, and even weeks, to grow slowly in length, and at the same time sends out club-shaped, slightly raised, grayish offshoots from its sides. In some of my cases the ulcer crept across the entire cornea, and, in a few others, in which several ulcers appeared simultaneously on different parts of the cornea, nearly the whole epithelial layer was eventually destroyed. As a rule, the ulcer shows no tendency to increase much in depth, and its floor and edges, although always of a bluish gray tint, are rarely opaque. The middle and inner layers of the cornea generally remain transparent throughout, but in neglected or maltreated cases an extensive star-shaped opacity of a slightly yellowish-gray tint is sometimes developed in the inner layers of the central part of the cornea.

"Of the various local remedies which I have used in this affection, none have afforded greater relief than the pressure-bandage, warm fomentations, and the sulphate of atropia. In addition to the local treatment I have always prescribed quinia and iron in large doses, and during the last two years I have given arsenic, generally in the form of Fowler's solution, in medium doses, in many cases with very beneficial results. In cases where the pain was great I have never hesitated to give morphium in sufficient quantity to give relief."

Dr. Knapp reported a case of one-sided complete blindness, from Ischæmia Retinæ, ended in perfect recovery, by the use of iron and outdoor exercise in the country.

Dr. S. Buller, of Montreal, Canada, remarked to the Society, that he had used nitrite of amyl, and thought it was of advantage in ischæmia of the retina. Dr. Webster had obtained better results from the nitrite of potassium. Dr. Knapp then read his second paper, entitled, "Eight Cases of Sclerotomy for Glaucoma."

Dr. Williams, of Ohio, reports "Two Cases of Cyst of the Iris," and dwells on the importance of early removal by surgical operation; he gives a very good wood-cut of a microscopic section. These cysts frequently require a second operation, but if they are neglected they produce entire destruction of the eye. Dr. Agnew, of New York, has a valuable paper on "The Insufficiency of the Ophthalmoscope as the sole Test of Errors of Refraction.

"Hence, in many cases of asthenopia, the only safe way to study the refraction is to pursue the following method:—

1. To examine the eyes first with the ophthalmoscope, and at the moment record the result.
2. To make the glass-test next and record its result.
3. To bring both eyes fully under the influence of atropia.
4. To test the eyes with the ophthalmoscope again, the eyes being under the influence of atropia.
5. To make a second glass-test, the eyes being under the influence of atropia.
6. To test the eyes with the ophthalmoscope and glasses at the end of ten days or two weeks, or when they shall have recovered from the effects of the atropia."

Dr. Knapp remarked that the use of the ophthalmoscope was certainly not the only means of determining the refraction of the eye, but that it was probably the best. He wished to point out those conditions in which its use would lead to fallacious opinions:—

First.—He had committed errors when the relief of the fundus oculi was irregular. *Secondly*, in astigmatism. If we examined the minute blood-vessels—those, for instance, which passed from the disk directly toward the yellow spot, we obtained the refractive condition of a particular meridian only (the vertical, in the above example), and we could appreciate the proper

degree of ametropia only by the successive determination of the refraction of fine blood-vessels that showed different directions. The third fallacy was the influence of the ocular muscles upon refraction, particularly in convergent squint, in which, without artificial paralysis of accommodation, we could determine only the far point of the relative accommodation.

Dr. John Green, of St. Louis, reports a case of "Detached Retina," treated by hypodermic injections of muriate of pilocarpin. He injected eleven millig. of muriate of pilocarpin, dissolved in half a cubic centimeter of distilled water, beneath the skin of the right temple. Salivation began within two minutes, and became profuse within four minutes. Sweating began at about the same time as the salivation; it was quite decided four minutes, and profuse seven minutes from the time of the injection. The pulse rose in the first two minutes, from seventy-six to one hundred and eleven, from which maximum it gradually fell to one hundred in the course of half an hour, at which time the salivation and sweating had both sensibly diminished. At the end of an hour the salivation and sweating were over, but the pulse remained at about ninety. The saliva was strongly alkaline, and the quantity ejected during the hour measured one hundred and twenty c.c. No trace of myosis or of accommodative spasm could be detected at any time.

The injection of pilocarpin was repeated, as nearly as possible as before, and was followed by the same train of symptoms. The patient was kept in bed two days and the dark bandage was kept on three days.

We pass a number of papers in the above Transactions which are chiefly occupied by descriptions of new instruments, modifications of old ones, which, before they are brought before the general profession must be subjected to trials by experts: such as combination set of trial glasses, by Dr. John Green: the Keratometer, a new instrument for measuring the curvature of the cornea, by Dr. E. G. Loring, of New York; an Instrument for the Detection of Color Blindness, by Dr. Wm. Thomson, by arranging the test skeins on a stick, the colors arranged alternately, to match the test; a modification of Loring's Ophthalmoscope, by Dr. Henry D. Noyes, of New York; Dr. Green, an Improvement in Concave spectacle Glasses of high power.

Cases of acute attacks of glaucoma have been in several instances reported as the result of the improper use of Atropia; and at page 148, Dr. John Green reports a similar result from the use of Duboisia, and Dr. Knapp, with many other good ophthalmic surgeons, believe, and we should practice, that mydriatics should always be avoided when there is a disposition to glaucoma.

So many cases of cataract operations require a new pupil, from the filling up with false membrane, that the majority require opening, and sometimes these secondary operations are as serious and of as much importance as the first. Dr. Edward G. Loring has devised the following improved operation—which consists, not in a simple opening in the centre of the iris, but in a large, free, and transverse section of the iris and all underlying membranes. The method of arriving at this result is as follows: "any narrow knife, such as the ordinary cataract-knife of Graefe, may be used, though the narrow blade suggested by Liebreich is preferable. Better than either, however, I think, is the knife which I have had constructed for this purpose. This is simply an extremely narrow knife, with a very delicate cutting edge. The reason why the knife is made so narrow is, that it may be turned on itself in the wound, at right angles, if necessary, with the position it occupied in making the puncture."

Dr. Henry W. Williams, of Boston, gave a brief account of his experience with the new operation for enervation of the eyeball—Opticociliary Neurotomy. He prefers "operating from the inner side, with division of the internal rectus, which may afterward be re attached to the globe by means of a point of suture. The use of Warlomont's scissors, which crush the retinal and ciliary vessels in dividing them, prevents or lessens the copious hemorrhage, which may cause marked temporary exophthalmos, and thus give rise to pain from distention of the lids and the intra-orbital contents. Should this happen, it soon disappears under the use of cold compresses, as does also the ecchymosis of the lids which generally follows the operation."

Dr. Green gives the details of a Modification of the Operation of Burow, for Entropion, with four woodcuts. For the details we would refer our readers to the Transactions. The especial value of Dr. Green's method depends upon points of detail in which it differs from the older operations, viz.: the preservation of the vascular connection of the loosened lid-margin through the muscular layer, the narrowness of the excised strip of skin, the manner of applying the sutures, and the use of collodion to glue the eyelashes against the front of the eyelid, thereby taking advantage of the leverage of the cilia as an additional and efficient means of maintaining the lid-margin in its corrected position.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1 60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE LIMITATION OF BIRTHS.

A question has been revived in a late number of the *Michigan Medical News* which has a great deal of importance in America, and about which there is a strange diversity of opinion among specialists in the branch with which it is particularly concerned.

It is well known that families of American parentage on both sides are generally small; it is stated on the best authority that the native-born American element of our population increases in number less than the foreign or mixed element; and it is quite certain that this relative diminution does not arise from a loss of virility in the male nor from a lessened fecundity in the female, but from a definite determination on the part of both to limit the number of their children, which is accomplished by preventing conception.

The results of this practice concern the political economist, the moralist, and the physician, in so far as these scientists have charge of the welfare of the community, and it is from the standpoint of the last mentioned that we would contemplate the question of the propriety of this course. In fact, the verdict of the physician must ultimately control the opinions of the two former, as nothing is in the long run harmful, physically, but that its tendency is immoral and injurious to the State.

Yet, strange to say, the editor of the *Michigan Medical News* states his opinion, that "this question does not properly pertain to medicine." He must have read but little in recent gynecological treatises, to pen such a sentence. There was a whole volume some years since published, on "Conjugal Frauds;" ten years ago Dr. STORER wrote a great deal on this subject, both for professional and general readers; a very startling chapter on "conjugal onanism" is given by Dr. GOODELL, in his "Lessons in Gynecology," to which we shall have occasion particularly to refer; and the alleged evils of this practice have been a favorite theme with a large number of writers of addresses, chairmen of committees on diseases of women, and such like gentlemen.

It is, therefore, a medical question, in the first instance, and it is also a living question, a question of the day, that ought to be discussed and settled, as to whether such practices are physically injurious or not, and if they are, to what extent and under what conditions are they so. There is a great cowardice in the American profession in discussing all such subjects, as we have frequently pointed out in referring to the matter of controlling venereal diseases.

There are men who will say that even if these practices are not injurious, or are but slightly so, still it is better to give the public the opposite impression, for moral reasons. As if a lie ever did or ever could benefit morality! As if deceiving a person who asks and pays for an honest opinion from a professional man is a virtuous act and in the interests of public ethics! Away with such shuffling sophistry.

The question is simply one of fact, and should be settled by observation and unprejudiced generalization, just as any other. So far as studying these facts are concerned, we should be perfectly indifferent as to any other consideration except the getting at the truth of them. Any man who thinks the morals of himself or his community cannot stand the truth, had better kick such morals out of doors, and go in for truth instead.

Dr. Goodell is one of the latest and strongest advocates of the opinion that such practices—all practices apparently which aim to prevent conception—are physically hurtful; in some degree to the man, in a far greater degree to the woman. (See Lesson xxxiii, "The Sexual Relations as Causes of Uterine Disorders; Conjugal Onanism and Kindred Sins," in *Lessons in Gynecology*, 2d edition). He gives a formidable list of diseased conditions which he has found in married women who acknowledged to have employed various means to avoid children. That in nearly every case it was, or might well have been, a *post hoc*, instead of a *propter hoc*, does not seem to occur to him; but the earlier part of the chapter is marked by such a strong prejudice on the subject, drawn from personal theological views, that one ceases to be surprised that even such a distinguished scientific observer, such a generally most admirable reasoner, gives way to his prejudices when they are so fervid. Even the conservative English critics could not approve of this part of his work. In a long and generally very favorable review of his volume in the London *Medical Times and Gazette*, the reviewer writes:—

> Perhaps the most novel feature of the book, and that in which it differs in the most striking manner from our English text-books, is the great importance which the author attaches to the abnormalities of the sexual act as causes of disease. Fibroids, polypi, ovarian cysts, fungous endometritis, prolapse of the ovaries, to say nothing of functional disturbances, are all put down to improper, or excessive, or deficient, venereal excitement. Not the slightest evidence is adduced here, nor, so far as we know, elsewhere, to demonstrate the connection. The fact that a number of Dr. Goodell's patients, who were suffering from the diseases in question, told him of irregularities of this kind, proves nothing, unless we could also find out how many people there were who exercised their sexual functions in the same unhealthy way and yet were not the subjects of any of these diseases. There is one class of women in whom the operation of these causes of ill-health may be reasonably supposed to be exceptionally frequent. If Dr. Goodell's doctrine be true, it is somewhat surprising that these diseases are not more common in prostitutes than they are. Either Parent Duchatelet was a most careless observer, or else his facts go far to negative the theories of our author.
>
> The fact cannot be denied, and the author above referred to knows it better than most of us, that the main causes of the diseases of women—those diseases which are peculiar to their sex—are *pregnancy* and *parturition*. Probably ninety per cent., at least, of the cases which seek the aid of the gynecologist trace their maladies to these conditions, their complications or their sequelæ.*
>
> Allowing, therefore, that certain means of preventing conception do have the results even which Dr. Goodell ascribes to them, would not

* The following extract is from an article on "The Uterine Function as a Cause of Disease," by Dr. P. V. Schenck, Surgeon to the St. Louis Female Hospital, in the St. Louis *Courier of Medicine*, February, 1881:—

"So intimately are gynecology and obstetrics connected, that a large proportion of female diseases take their origin in the lying-in room. Mismanaged labor is the cause of much of the gynecological practice. Uterine diseases, says Mundé, are, in the large majority of instances, the direct result of parturition. Thomas, in confirmation of this, remarks that if we go back to the commencement of all cases of uterine disease, a very large proportion will be found to date from parturition."

Add to this "large proportion" the accidents and complications of pregnancy, abortion and miscarriage, and ninety per cent. is probably not too high a figure.

pregnancy and parturition, if allowed to proceed in these same cases, have induced yet more numerous and troublesome maladies? Unquestionably so. Therefore, even on his own grounds, looking at the physician's duty to be, in the first instance, the physical well being of his patients, would it not be rather to state this fact than to convey the impression that the reverse is true?

We are well aware that in certain individual cases pregnancy is a curative measure for uterine difficulties; but we speak of the average, and what is true of the majority.

But in the *Medical News*, Dr. O. E. Herrick, a gynecologist of repute, goes further. He says there are means of preventing conception which are absolutely harmless to the woman, and, to quote his vigorous colloquialism, "all this mawkish sentiment about its being wrong, or about its doing damage to the health, is simply bosh."

This, too, is the opinion of the French gynecologists, in whose country the limitation of families is carried to a system. No such results are mentioned in their treatises as the American author quoted has imagined he has found. There are means familiar to all physicians any hurtfulness in which would seem difficult to understand. There are others which no doubt are injurious, if repeated for a long time. It would seem, therefore, that if any advice is given on this subject—if any pay is accepted for a professional opinion upon it—the truth ought to be told to the inquirer, as near as we know it. At any rate, it is an assured conviction with us, that one might as well expect to gather figs from thistles as to operate for a moral effect by conveying impressions contrary to our own convictions of the truth.

As to the effect of a general adoption of means of limiting families in society at large, the best authorities differ *toto cœlo*. The one school of writers, those who believe, with Malthus, that unless there are preventive checks the population will soon outgrow the food supply, point to many instances where such is actually the case. The other side explains these examples by various suggestions of how easily they might have been prevented.

The French statisticians generally bewail the small size of families in their country; yet it is well known that France, in spite of her losses, is a richer country than Germany, and her lower classes are better off than the lower classes in England.

The *République Française* has lately published a series of elaborate statistics, which show, conclusively, that the population of France has been steadily on the decline for the last two hundred years—a state of things which it thinks deplorable. It considers that the rapid increase of population is not only an element of military strength, productive power, and intellectual superiority, but points out that one of the consequences of this waning population is dearth of labor. France has to import, at considerable expense, laborers from Belgium and Italy, for agricultural and industrial purposes. The cause of the evil, it asserts, is to be found in the fact that French marriages are unfruitful, and it is a serious danger for the political and military power of the country.

It is needless to add, that the British school are generally opposed to limited families, just as they are to any restrictions on the indulgences of the appetites:—

"To urge," says Professor Bain, "that there is sufficient poverty and toil in the world without bringing in more to share it than can be provided for, implies either begging the question at issue—a direct imputation that the world is at present very badly managed—or that all persons should take it upon themselves to say how much poverty and toil will exist in any part of the world in the future, or limit the productiveness of any race, because inadequate means of feeding, clothing, or employing them may be adopted in that part of time sometimes called unborn eternity. As a rule, the result usually has been, limit the increase of population without adequate cause, and the reaction causes deterioration or annihilation."

To this, it is answered, that confessedly the world *is* very badly managed, and the most man can do is to make it barely tolerable for the greater number; secondly, that in declining to beget, to the utmost of his power, a man or woman does not and need not consider the whole

world, but his own circumstances; and thirdly, that the deterioration and annihilation referred to is a mere rhetorical picture, no such thing appearing anywhere in history.

But this pure political side of the question may be left to other places for discussion. Enough to say, that it is an open question, not to be shut off by bold assertion.

Notes and Comments.

On a Question of the Day.

Our readers should take an interest in the effort which is making in this and other cities to oppose trade-marks and copyrights in manufacturing pharmacy. The question arises in the main from a belief that the public are often defrauded and the emoluments of the profession diminished by these legal protections to specialties.

Whether this is the case to a marked extent, and whether, on the whole, the disadvantages to the profession and the public overbalance the advantages, are the points at issue; and they are not yet decided.

Two years ago (Reporter, March 8, 1879, p. 216) we quoted, approvingly, the opinion of Dr. Mott, of New York, that trade-marks are "the best protection the public can have." We argued that, if properly guarded by statutes against abuse, copyrights and trade-marks in pharmaceuticals, and patents in surgical instruments, are just as advantageous to the public and the profession as to the manufacturer; and from this opinion we have as yet seen no sufficient reason to depart.

Turpentine in Psoriasis.

At a meeting of the Medical Society of London, Dr. Radcliffe Crocker showed a case of general psoriasis, illustrating the comparative result of treatment by turpentine and chrysophanic acid. The patient, a man aged forty-six, had never been entirely free from the disease for fourteen years; a soft cancer ten years before was not followed by constitutional disease, and the psoriasis presented the usual typical character of the now specific eruption. The disease was worse in winter; the last attack began in November last. With the exception of the lower part of the face and scalp, the middle of the back between the crest of the ilium and the line of the angles of the scapulæ, and the backs of the thighs, the eruption was so closely distributed that there was scarcely any interval of healthy skin; over the knees and elbows the patches were larger. The treatment adopted was, first swathing him in bandages soaked in oil for four days, to remove the scales; the left half of the body was then rubbed with half a drachm of chrysophanic acid to one ounce of lard, while the right half was rubbed with two drachms of oil of turpentine to one ounce of olive oil. The strength of each preparation was increased every few days, until pure turpentine was applied on the right side, and chrysophanic acid, one drachm to the ounce, was used to the left; and in twelve days from the time this strength was reached the whole eruption on both sides had disappeared, with the exception of a few spots on the shoulder. As far as rapidity of action was concerned there did not seem any advantage of one application over the other; there was a little tingling with the turpentine, while the chrysophanic acid produced staining of the clothes and skin.

The Cause of Nephritis after Diphtheria.

The nature and mode of production of diphtheritic nephritis is the subject of a recent communication by M. E. Gaucher to the Société de Biologie of Paris. It may be expected that the lesion would be due to the same mechanism as that which produces the similar changes which have been found in some other infectious diseases. In the nephritis which sometimes occurs in typhoid fever, for instance, there is a granular infiltration of the epithelial cells and an obstruction of the lumen of the tubules of diffused material or globular masses. These alterations have lately been ascribed by Bouchard to the infiltration of the kidney by bacteria. In a case of diphtheria which Dr. Gaucher had an opportunity to examine similar bacteria were found in the blood and kidneys. From these facts he concludes that diphtheritic nephritis is of parasitic origin, and that the albuminuria is the result of the passage of the bacteria of the blood through the kidneys. The albuminuria is thus to be regarded as an effort at the elimination of the poison.

Statistics and Treatment of Ophthalmia Neonatorum.

At a meeting of the Manchester (England) Medical Society, Dr. Emrys-Jones gave the details of 420 cases presented for treatment at the Royal Eye Hospital, a large proportion of which had been under previous treatment. In 72, or nearly 18 per cent., the cornea was affected; in 38, both corneæ were affected; in 34, one cornea was affected; in 16, both eyes were lost; in 21,

one eye was lost; making a total of 53 eyes lost, or nearly 6¼ per cent. In 26 cases there were ulcers of the cornea; in 14 cases there was perforation, 6 with prolapse of the iris; in 16, there were large opacities; in 5, there were ulcers with lead deposits; in 4, there were ulcers with deposits of nitrate of silver. Dr. Emrys-Jones stated that he had never seen a single case of uncomplicated ophthalmia neonatorum lost where proper treatment was adopted early. He further pointed out that, after inquiry into the cause of blindness, in 72 cases examined for admission to Henshaw's Blind Asylum, 24 of them were found to be due to this disease in infancy, and that 75 per cent. of all the blindness in this large asylum were due to preventable causes. After referring to Dr. de Wecker's method of treatment with 2 per cent. solution of carbolic acid, he detailed the method he found most efficacious, viz: brushing the palpebral conjunctiva over with weak solutions of nitrate of silver, 10, 15, or 20 grains to the ounce of water, by means of a camel's-hair brush, and washing off the superabundant nitrate with a solution of salt and water.

Special Reports.

NO. VIII—SURGICAL MECHANICS.

The ingenuity of American inventors is justly famous, and American surgeons are by no means the last in this department. Owing to some disappointments with cuts the present is only a preliminary report in this important branch.

Artery Forceps and Needle Forceps.

Dr. J. S. Wight, of Brooklyn, has laid before the profession, in the Proceedings of the Kings County Medical Society, two ingenious forceps. He writes:—

I invented the *artery forceps* in 1872, for the purpose of taking hold of meningeal arteries when required during resection of the cranial bones. The curve in this instrument is adapted to this work, in which I have used it several times. The length of the instrument is four and three-fourths inches. The jaws are curved, and have a length of about an inch and a half. The jaws are perforated near the ends, so as to introduce a ligature for arteries or tumors. I use this instrument constantly, to arrest hemorrhage during operations, especially during operations on the head. When the operation is done the artery forceps is removed, and generally the hemorrhage does not recur. I have used it in ligating arteries in the continuity, and in ligating arteries during all kinds of amputations. The curve of the instrument will seize a considerable extent of bleeding surface and arrest the flow of blood. This pair of forceps I consider a valuable adjunct to the ordinary artery forceps. It has a spring catch and a pivotal pin, which has enabled me to use it as a handle to the chain-saw, so that I have dispensed with the usual handles.

I invented the *needle forceps* in 1873, as none of the needle forceps in use exactly suited me. This instrument is about five inches in length, having straight jaws about an inch and a half in length. On the inside of the handle rings it has a catch, that can be easily operated with one hand. The arms of the handles are somewhat elastic, but yet enable the jaws to grasp the needle firmly. I have pushed a pin through a half inch pine board with this instrument. I have used the needle forceps for the avulsion of ingrowing nails and removing pieces of necrosed bone. One of the most important uses of this instrument is the arrest of hemorrhage. In 1874 I suggested the use of the needle forceps for the arrest of bleeding from the axilla, in a case of my

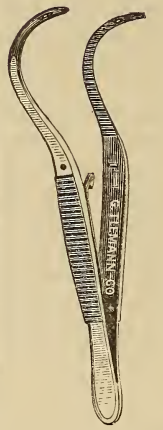

Fig. 1.

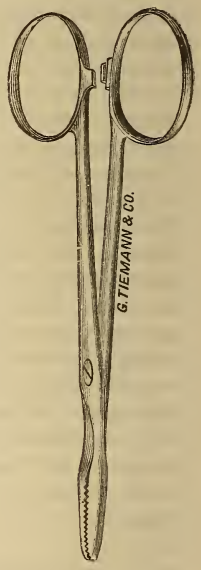

Fig. 2.

colleague, Dr. Skene. The Doctor was removing a large tumor from the breast and axilla, and had a gush of blood from the axilla, with extreme difficulty of ligation. My needle forceps were applied to the bleeding vessels, and left in place for thirty hours, and then removed, when bleeding did not recur. The Doctor tells me he has often repeated this experiment. Since that time I have used the needle forceps for hemostasis. I have also used the needle forceps for crushing the ends of arteries of the scalp, in case of failure of other means. I have used this instrument for crushing the veins in some cases of piles, and had a most desirable result follow.

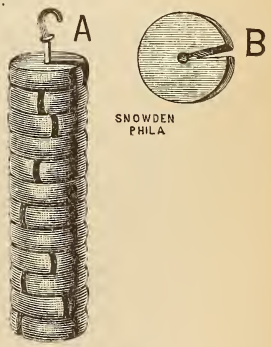
These instruments are made by Tiemann & Co., 67 Chatham St., New York. Fig. 1 represents the artery forceps. Fig. 2 represents the needle forceps and hemostat. I would long ago have published descriptions of these instruments, but have waited till experience has fully demonstrated their uses, some of which I have pointed

out. They will shorten operations and prevent loss of blood, and thus be the means of saving life.

Extension Apparatus for Fractures, etc., of the Bones of the Leg.

In the treatment of fractures of the tibia and fibula, coxalgia, etc., there was not, till recent years, any form of apparatus employed by which an equable, and at the same time a *reasonable*, amount of extension could be exerted. In our hospitals and private practice, reliance was placed upon bricks, weights, or, in fact, anything that came most readily to hand, and that could be made to do duty as an extending force. The subject of the measurement of the amount of extension in cases of fracture is to the practitioner a very important one in these days, when every case of fracture treatment undertaken has standing back of it the threat of a suit for malpractice; for in the event of such a suit, the question may be presented, as to what amount of extension was placed upon the limb; that could not be very satisfactorily answered by the reply "two or three bricks," the weight of which bricks is a mere matter of guess and approximation. Some years since Dr. Levis, of this city, prepared a form of apparatus that has enjoyed a very high degree of favor in the treatment of leg fractures. This consists of two portions, a rope and pulley, by which weights are suspended, and a cage, or iron bar, to support the weights. As originally constructed, the apparatus may thus be described. An upright iron rod supports a pulley, over which plays an extension cord; the prongs of the fork-like portion of the bar in which the pulley plays should fit close to the wheel, and project an inch to an inch and a half above the top of the wheel, in order that the extension cord may not be readily thrown out of place by those passing in close proximity to the bed; in fact, we rather think if there was a top piece connecting the two upper ends of the fork in which the pulley plays, that it would improve the apparatus by preventing any possible dislodgment of the cord. To hold the upright bar in position an adjustable clamp is employed, by which the rod and pulley can be adjusted to any required height, while at the same time the clamp will grasp a bar of any width at the foot of the bedstead, or, in fact, it may be attached to any body that will afford sufficient security and steadiness; this clamp may be reversed, so as to grasp an under surface as readily and strongly as an upper. The amount of weight extension is effected by a series of one pound weights, through the centre of each of which is drilled a hole, these weights sliding on a rod bent into the form of a hook at the top, for catching in a loop in the extending cord, or they may rest in a cage, composed of four upright iron bars, from which they may readily be removed by tilting them on their edges.

As originally constructed, this apparatus presented with all its advantages one disadvantage, namely, that to decrease or increase the amount of extension it was necessary to remove the weights from the extending cord and to slide them up or down over the bent extremity of the bar; further, if the weights were so slotted as to be placed on the bar without passing over the hook, then they were liable to be thrown off if accidentally struck; in the same way a blow on the cage form of the apparatus might result in the tipping up and rolling out of the weights, which, as can readily be seen, is not a desirable consummation. Taking these things into consideration, the apparatus has been somewhat modified recently, by Mr. Snowden, an instrument maker of this city. This modification consists in flattening and narrowing the diameter of the upper inch and a half or two inches of the bar upon which the weights are suspended, the remainder of the bar maintaining a uniform diameter. In the centre of the weights a hole is then drilled, into which the rounded portion of the bar fits very tightly, and from which centre hole a slot is cut (B) that, while it permits the passage of the bar in the upper constricted and flattened portion, is too narrow to allow of the weights slipping off the bar, no matter in what direction or with what force a blow may be struck or the apparatus displaced. The amount of extension, which, during the first few days, in the treatment of fractures in muscular adults, should be about twelve pounds, can thus be readily diminished to eight pounds or less; the body being employed as the counter-extending force, a perineal band being employed if necessary, the foot of the bed, of course, being somewhat elevated.

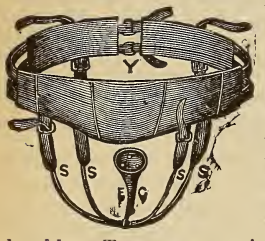


The cardinal principles of an extending apparatus are, we think, thus obtained, namely, convenience in form and inexpensiveness, portability, ready and convenient adjustability to

various forms of bedsteads, and an accurate measurement of the amount of extension exerted and ease of readily varying the amount of extension. The measurements of the apparatus are as follows: greatest length of perpendicular bar from tip to tip, 23 inches; transverse measurement, $\frac{3}{8}$ inch; size of wheel, $2\frac{1}{4}$ inches; length of clamp over top, $3\frac{1}{2}$ inches; length of binding screw, $4\frac{1}{2}$ inches; length and width of clamp tongue, $4\times1\frac{1}{4}$ inches; weight, 14 pounds; extreme length of rod for weights, $11\frac{1}{2}$ inches.

Combination of Stem Pessary and Abdominal Belt.

The improvements in gynecological surgery are as numerous as in any other branch, if not more so. The present cut illustrates one of Staufer's series of improvements. The hip straps are elastic, being of the material known as "satteen," which is a woven tissue of fine quality and durable. The stem cup is of hard rubber, and through its base the soft-gum attachments *s s s s* pass, fastening it to the belt. This allows adjustment so that the stem can be made to meet the axis of the vagina. The rigidity which has been objected to stem pessaries fastened on an inflexible metal rod, is happily overcome by this contrivance.



Correspondence.

A Visit to the New State Insane Hospital, near Norristown, Pennsylvania.

Ed. Med. and Surg. Reporter:—

Pennsylvania, the keystone of the federal arch, has been justly celebrated as one of the chief cultivators of the arts of peace and good will to all mankind; her coal, oil and iron, have built up the commercial prosperity, not only of the State, but of the whole Union. In all the benevolent and philanthropic efforts to improve, ameliorate and benefit mankind, she has been always in the front rank. This State has been also careful of the poor, the blind, halt, and the lame; as well as the deaf, dumb, and insane. This latter class makes the strongest and most urgent appeals to the sympathies and benevolence of her people, and she has not been lukewarm in providing for their wants.

The first State Lunatic Hospital was established at Harrisburg, in 1851; but in spite of all the care and attention given to its administration, it was not sufficient to accommodate the increasing number of patients that were constantly applying for aid, nor was there sufficient space to properly classify those that were received, to give the best opportunities for cure.

The Western Pennsylvania Hospital, at Dixmont, near Pittsburg, was opened in 1856. This is a general hospital, and like that at Philadelphia, has also a department for the insane.

The second State Hospital for the Insane was, therefore, built and opened November 1st, 1872, at Danville, with a total capacity of seven hundred. In the above Institution there is a board of trustees, who meet once a month, or oftener, but the physician is the chief executive officer, not only attending to his own special duties, but also all the others. Again it was found that the capacity of this hospital was not sufficient for all the demands, and the insane department of the Philadelphia hospital was so crowded that it became unfitted for the proper treatment, so that the present hospital for the Southeastern District of the State had to be built. It has been in operation one year in September, and the number of patients in the hospital is six hundred and ninety-four, its full capacity being seven hundred. Part of the patients now in the wards had to be removed from the hospital at Danville, owing to a recent fire that destroyed one half of that building. The hospitals at Harrisburg, Danville, and Philadelphia are all under the old system of a moderate amount of restraint, the chief physician being a male.

This new hospital, near Norristown, is under the system borrowed from those of Belgium—small, separate buildings, with no restraint but the watchful care of the nurse or attendant; all the patients are free, inasmuch as no sort of wristlets, strait jackets, muffs, etc., are used; and even the very noisiest and most excitable patients were, with one exception, allowed to walk about during our visit. On careful inquiry about this class—some of whom are very destructive, and some have a suicidal tendency—we were told that the day previous one of the men was about to attack Dr. Cass; he had his coat off, and the Doctor, looking him in the eye, inquired about the weather, and so the patient's attention was diverted. Another case, in which Miss Alice Bennett, the physician who has entire charge of the female patients, with an assistant, Miss Anna P. Kugler, were going through the ward, a violent woman sprang at the former, and would have hurt her, had not the attendant caught her and placing her arms round her passed her into her room and locked the door.

Sufficient time has not elapsed to be able to judge of the working of this free system and the division of labor of male and female departments, and we prefer to give a few extracts from the joint reports of the two chief physicians. When the report was made, Oct. 1st, 1880, the whole number of patients was 544—241 males and 303 females, native born and foreign. The chief alleged physical cause of insanity in the males was intemperance, and the chief moral cause, domestic trouble. The chief form of insanity was chronic mania, of which there were 111 cases; then followed dementia, 113. There were 14 who had a homicidal disposition. The mortality from July 12th, 1880, to September 30th, 1880, seven cases. Discharged from institution, two recovered and one improved. During the month of August there was admitted into the men's ward of this hospital the almost

unprecedented number of 227 patients, ranging from the mildest to the most active and dangerous types of insanity. Not a single accident occurred. Of this number, 125 were from the Insane Department of the Philadelphia Hospital. Subsequently, 140 more were received, making the whole number of patients Philadelphia has supplied and is paying for, 265, which makes the hospital, although somewhat removed beyond the city limits, practically a Philadelphia institution.

The institution is constructed on the plan of detached wards and supply buildings, with connecting corridors—the first two male ward buildings are parallel to each other, on the linear plan, the second one receding in the usual manner, except that it is entirely detached from the first; the third building is situated at right angles to the others, and the fourth or refractory ward building is built upon lines running parallel to the first. The hospital faces the southeast side, which gives a plentiful amount of sunshine in the wards both morning and afternoon. The buildings for patients are two stories in height, and within are light and cheerful in every part. The number of wards are sufficient (sixteen for males) to admit of a very thorough classification of the different grades and types. The institution has most of the modern improvements in hospital appliances, both in and out of the wards, and many minor devices and conveniences which are peculiar to itself.

Dr. Cass writes: "One of the older Asylum Superintendents once remarked that the most important consideration in the care and treatment of insane patients in hospitals is the provision for the violent class. While this institution will rank favorably in most respects with any, it is in the wards intended for the untrustworthy that the most admirable adoption exists.

"The term moral treatment is used to designate all of the restorative means that are employed in the treatment of the insane aside from medical agents, and in this division occupation and amusement are the main resources.

"Employment prudently selected and conducted is especially regarded as an important curative means in insanity. As such, it will be turned to account. Already there are employed in various ways about the hospital nearly one-third of the whole number of male patients, and this force will be increased judiciously from time to time."

In the female department, the report of Dr. Alice Bennett states:—

"In this period of two months and nineteen days 201 patients were admitted. Four patients have been discharged recovered; all were inmates of the hospital for less than two months; the whole duration of the disease, in three cases, did not exceed three months; one had been an inmate of another hospital for eight months, and for her change of scene seemed to work a benefit as sudden as it was gratifying. Six deaths have occurred. Realizing the value of the 'moral treatment' of mental disease, realizing, also, that this consists more in the every day—and every hour—influences brought to bear upon each mind than in any special devices for their occasional diversion or entertainment, however important these may be as aids, it has been the aim of the Trustees and medical officers to secure a high order of service in the wards, and in this they believe they have been, in some measure, successful. It is aimed to make each ward a home, whose influences shall be elevating, and where justice and kindness to all are assured. Work is encouraged as a sovereign remedy. Various means of occupying and interesting patients, to be found in the older institutions, are lacking, but with sewing, plain and ornamental, reading, which has been supplied in limited quantity by a few friends, the general work of the ward, with occasional days at the laundry and kitchen, the time has not seemed to hang heavily, and a general spirit of contentment has pervaded the wards."

"In the treatment of the excited class, mechanical restraint has been used in a few cases only, and is now, practically, in disuse. Several 'violent' cases, brought from other institutions under some form of restraint that had become habitual from months of use, have been released at once upon their admission, with most satisfactory results.

"Nothing is more certain than that mechanical restraint is incompatible with 'moral treatment,' and that resort to it destroys at once any personal influence that might otherwise be brought to bear. Whether a confession of fear on the part of the attendant, or a substitute for the latter's vigilance, it can hardly fail to lessen the bond of respect between patient and attendant, which it is *essential* to preserve. The patient is humiliated by her chains, and often the most vicious propensities are aroused. For example: Among the cases referred to was a woman whose hands had been confined by 'the muff' for six months continuously. As a consequence she had learned to use her feet with a force and accuracy of aim that made them far more effective weapons of offence than her hands could be, and by the simple release of the latter she was at once a less dangerous companion for other patients. By judicious firmness on the part of attendants, who must know no fear, never get in a passion, but treat the patient with uniform kindness, and, above all, with uniform justice, patients like the one described may be brought under control as much more complete and efficacious than mere mechanical restraint, as it is higher and more desirable. Too much cannot be expected. Untrained, savage natures, which have never known self-control, will not at once respond to the higher stimulus. These require the utmost vigilance and the utmost patience, but surely each of the lowest and apparently most hopeless of these unfortunates may claim our best endeavor.

"I would not be understood as placing myself among the radical advocates of non-restraint. In some rare cases restraint may be justifiable as a protective measure; I have even heard it said that it is sometimes remedial; but is not the good it *may* do so surely modified by the evil it *must* do as to lead all thoughtful persons to pause and carefully balance the two before resorting to it?"

The Hospital building No. 1 of the original plan, intended for violent female patients, was

not erected, by reason of a lack of funds. Consequently, another building, not adapted to the treatment of this class of patients, is now being used for that purpose. The natural increase of patients has filled the female wards, and it is therefore essential that the No. 1 building be erected during the coming season. There are many other improvements needed to complete the plan devised for this Institution, for all of which the following estimate is made:—

No. 1 building, corridor, etc	$95,000
Grading, drainage and roads	10,000
Fencing	7,500
Exercising yards	3,000
Ice house, dam and slaughter house	4,500
Coal bin and track	1,500
Barn and root house	5,000
Porter's lodge and entrance gate	5,000
Screens for windows	1,500
Covering for corridors	20,000
	$153,000

An appropriation of $20,000 will be needed for additional furniture and equipment, and $5000 for farming stock and utensils.

The Legislature has been asked to appropriate $150,000 for this purpose. Several members opposed the appropriation, on the ground that it was not absolutely necessary, and to convince them to the contrary, an invitation was extended to them and others, by the trustees, to visit the Institution, on Saturday, March 19th, and make a most careful and thorough examination of the whole building, which they did, and from the tone of their remarks we were entirely satisfied that they would make the appropriation. The Institution is under an admirable non-partisan set of trustees, many of them devoting much of their valuable time and talents to it, and we feel that it will ultimately prove a great boon to the class of society for which it was built. Several well known medical gentlemen are connected with it, and the following were in attendance, in spite of a pouring rain: Dr. John Atlee, of Lancaster, who made an admirable speech, Dr. Arnholt, of Pittsburg, and Drs. Diller Luther, Laurence Turnbull, N. L. Hatfield and Weist of Philadelphia, Dr. Kern, of Bath, and Dr. Martin, the able Secretary, of Allentown.

Much kindness and courtesy was received by your reporter, and he desires to express his thanks to the President, General Hartranft, and Treasurer, B. K. Jamison. Esq., also the Chairman of the Executive Committee, W. D. H. Serrill, Esq., of Darby, and other members of the Board of Trustees. L. T.

News and Miscellany.

Medical Society of the State of Pennsylvania.

The Thirty-second Annual Meeting will be held in the city of Lancaster, on Wednesday, Thursday, and Friday, May 11th, 12th, 13th, 1881, commencing on Wednesday, May 11th, at 9 A.M.

Appointments for 1881.—To make the address in Medicine, Dr. J. Solis Cohen, Philadelphia. Surgery, Dr. S. M. Ross, Altoona. Obstetrics, Dr. S. T. Davis, Lancaster. Hygiene, Dr. Benjamin Lee, Philadelphia. Mental Disorders, Dr. S. S. Schultz, Danville.

Committees.— On Epilepsy and Insanity, Dr. John Curwen, Harrisburg. On State Board of Health, Dr. Wm. B. Atkinson, Philadelphia. On Medical Legislation, Dr. R. L. Sibbett, Carlisle.

Amendments to be acted on.—By Dr. W. W. Dale—Constitution, Article V, Section 5. Add: "Which action shall be final; provided, however, that either party may appeal to the President of the State Society, who may direct the Censors of an adjoining district to hear and determine the case, and to report their action to the Society, which shall be final."

By Dr. C. A. Rahter—Article IV, Section 1. After the word Treasurer, add: "Judicial Council."

Also, By-Laws, Article 1, substitute for Section 10: "A Council, consisting of nine members, shall be elected, whose duty it shall be to take cognizance of and decide all questions of an ethical or judicial character that may arise in connection with the Society. Of the nine members of the Council first elected, the three first named on the list shall hold office one year, and the second three named shall hold office for two years. With these exceptions the term of office of members of the Councils shall be three years, three being elected annually.

"The said Council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said Council, on all matters referred to it by the Society, shall be final, and shall be reported to the Society at the earliest practicable moment. All questions of a personal character, including complaints and protests, and all questions on credentials, shall be referred at once, after the report of the Committee of Arrangements, or other presentation, to the Judical Council, and without discussion."

By Dr. J. T. Carpenter—Article III, Section 2. "The delegates shall receive their appointments from the County Societies, and from the College of Physicians of Philadelphia."

Resolution adopted at Session of 1880.—That no delegates from a County Medical Society be allowed to take seats at the session of next year unless they bring evidence of having complied with the law requiring the appointment of Medical examiners. *Vide* Transactions, 1880, p. 21; Transactions, 1878, p. 23.

☞ Secretaries of County Medical Societies are earnestly requested to forward *at once* complete lists of their *Officers and Members*, giving the *post-office address of each.*

Every *delegate*, before admission, shall produce a certificate of delegation, signed by the President or Secretary of his County Society.

Every *permanent member* (*not a delegate*), before admission, shall produce a certificate of good standing in his County Society.—(*Extract from Constitution.*)

WM. B. ATKINSON, M.D.,
Permanent Secretary.

—Cerebro-spinal meningitis of a grave type has prevailed in the Mississippi and Ohio Valleys the last few months. In Southern Indiana it has been almost epidemic.

International Medical Congress, London, 1881.

Preparations for the approaching International Medical Congress are being vigorously pushed forward by the Executive Committee, and the arrangements are now beginning to take a more definite form.

The inaugural address, by Sir James Paget, the President-elect of the Congress, will be given in St. James' Great Hall, which has been already engaged for the purpose, on Wednesday morning, August 3d.

The following mornings will be devoted to the business of the various sections, while the afternoons (with the exception of Saturday afternoon, which will be left free for garden parties, excursions, etc.) will be occupied by the general meetings of the Congress, at which four addresses will be given by distinguished men of four nationalities. Three gentlemen have already promised to give these addresses: Prof. Huxley, probably on "The Connection of General Science and Medicine;" Prof. Volkmann, of Halle, on "Modern Surgery;" and Dr. Billings, of Washington, on "Medical Literature." The fourth address, to be given by a distinguished Frenchman, has not as yet been finally arranged.

The meetings of the various sections will be held in rooms at Burlington House, courteously placed at the disposal of the Committee by the University of London, the various learned societies and the Royal Academy of Arts. This, however, not providing the required amount of accommodation, the Committee have engaged Willis' Rooms for the occasion, and four of the sections will hold their meetings there.

As stated in an earlier notice, no less than 40,000 individual medical men in various parts of the world received the original circular of invitation during August and September of last year, and since then the secretaries of the various sections have been actively engaged in circulating provisional lists of subjects, which seemed, in the opinion of the committees of the sections, those best suited for discussion and papers. Numerous replies have been received in answer to these communications, in some cases leading to alterations in the subjects selected. These amended programmes have again been distributed among those most likely to take interest in them, and are now combined into a pamphlet and are issued, together with the rules of the Congress, printed in the three official languages, to any medical man making application for them to the Secretary General.

Since the list of names published in November last, a large number of our foreign colleagues have definitely announced that they will come to the meeting, and there seems every prospect of the attendance from abroad being a full one. Meanwhile, depending on the number of names appearing as officially connected with the Congress, and on the subscription list, together with the number of gentlemen from abroad who have positively stated their intention to attend, a certain estimate of 1000 members may be made, and it seems not unreasonable to assume that at least double that number will attend.

The Reception Committee are busily engaged, and have decided upon giving an evening Reception at South Kensington, and perhaps a second in the Albert Hall.

The Lord Mayor purposes entertaining members of the Congress at dinner at the Mansion House, on August 4th.

The Sanitary State of New York City,

A remarkable statement concerning the actual and prospective healthfulness of New York City was made by Professor A. L. Loomis, at a meeting of the New York Academy of Medicine, March 18th. As the sanitary character of that metropolis is a subject of general interest, we reproduce a portion of it. Dr. Loomis said: It is hardly necessary for me to remind the members of this Academy that during the past few months all diseases, acute as well as chronic, assumed an unusually malignant type. By reference to our death-rate, we find that during those months it has been higher in New York City than ever before during the corresponding months of the year. The disease which is to be before us for discussion—pneumonia—has prevailed more and more fatally than ever before since I have been a member of the profession. There have been fevers which cannot be classified—new in many respects—prevailing among us. Phthisical patients have passed away in ways to which we were not accustomed, and when persons in the declining years of life have been seized with acute diseases, every physician must have trembled at the results. There has been a peculiarity, a fatality, in the types of disease which must have struck every practitioner as unusual. As guardians of the public health, it seems to me that we are very naturally led to inquire what are the circumstances and what the conditions which have brought this condition of things about. Has disease changed its character, or has there been a weight upon the city which it never felt before? As suggestions to answers, I would make the three following propositions, not with the idea that they will answer all the indications or account for all the conditions: First, we should remember that the city of New York is in a malarial district, and its inhabitants, on that account, are predisposed to disease; secondly, we all know that our sewerage system is notoriously bad and deficient, and we also know that there are emanations from the sewers which are deadly in their nature, and that when these shall be thrown into our homes and streets by defective sewerage, we have another element added to the malarial element which is a powerful producer of disease; and, thirdly, during the past three months there has been a mass of animal and vegetable matter undergoing decomposition in our streets in connection with the melting snow and ice. These conditions, sanitary science teaches us, are most prolific for the production of disease. Now, when we come to add these three factors together—to unite them—is it strange that there should have been great mortality in this city? And, sir, unless a change is effected—unless the causes for the production of disease are removed—I predict, as the coming months pass on, that an epidemic will sweep over the city

which will arouse the citizens from their lethargy in regard to sanitary measures.

The Plague.

This scourge has been ravaging the banks of the lower Euphrates and the villages of Mesopotamia. Quarantine against it has been declared by the Egyptian authorities. In spite of this it is said already to have crossed the Mediterranean, and one or more deaths from it have been reported at Seville, Spain. The littoral cities of Southern Europe are by no means in such superior sanitary condition that all danger is averted of another experience such as Marseilles had in 1722.

Philadelphia Academy of Surgery.

At the next meeting, Monday evening, April 4th, Dr. J. C. Hutchison, of Brooklyn, will read a paper on "The Treatment of Hip-joint Disease."

Personal.

—Dr. Robert S. Ives practiced medicine in New Haven, Connecticut, more than a hundred years ago, and his son, grandson and great grandson, nephew and grand-nephew have all followed the same profession in the same city, bringing the record down to the present day without interruption.

—Dr. Daniel F. Kimball, made notorious by his connection with the Lynn, Massachusetts, trunk tragedy, died in the State Prison at Concord, on Tuesday, March 22d, of a complication of diseases. He was about forty-three years of age. His sentence was for seven years.

OBITUARY NOTICES.

—Dr. Charles Osgood, a prominent citizen of Norwich, Conn., formerly Mayor of the city, and President of the New London Northern Railroad Company, died, March 19th, after a long illness.

—Dr. Horatio Nelson Loomis died in Buffalo, on March 23d. He was born in Franklin, New London County, Conn., March 25th, 1807. His father came West and settled in Sangersfield, Oneida County, New York, when Horatio was five years old. He attended four full courses of medical lectures at Fairfield Medical College, in Herkimer County, New York, commencing in 1824. He was graduated in January, 1828, and in the following April settled at Palmyra, Wayne County, in company with Dr. Gain Robinson and his son Cassius. He continued with them three years, when the elder Robinson died and the younger removed to Michigan. Dr. Loomis was immediately joined by the late Prof. Delamater. The copartnership continued for five years. Dr. Delamater removed to Cleveland, Ohio, and Dr. Loomis went to Buffalo, in 1836.

—Colonel Thomas A. Scott, of this city, has presented $50,000 to the Jefferson Medical College, $30,000 to the Orthopædic Hospital, and $20,000 to the Children's Department of the Episcopal Hospital.

QUERIES AND REPLIES.

An Ethical Question.

Dr. A., being sick, calls Dr. B. to see him, and requests Dr. B. to assume the charge of his patients.

Patient No. 1 is sick at the house of one of Dr. B.'s families. Dr. B. has received from Dr. A. his diagnosis and course of treatment. Dr. B. calls on patient and diagnoses an entirely different disease. Dr. B. tells the patient and family that Dr. A.'s diagnosis is incorrect, and gives reasons for the correctness of his own diagnosis. Dr. B. changes treatment to suit his own diagnosis, and then informs Dr. A. of his diagnosis and change of treatment.

Dr. A. calls next day, receives his pay and the comforting assurance "if we want you any more we'll let you know."

Question 1st. Was it proper or ethical for Dr. B. to contradict Dr. A.'s diagnosis, and to detail his own diagnosis to the patient and family?

2d. If Dr. B. differed with Dr. A., would it not have been ethical to detail that difference to Dr. A. and to no one else?

Ans.—It was evidently very unethical for Dr. B. to take such action.

Dr. S. P. R., of Pa, writes:—Can you inform me whether, in the manufacture of pepsin preparations, beef extracts, peptones, dry blood, etc., sufficient heat is used to destroy the vitality of the cysticerci of the tænia, or ova of other parasites which may be present?"

Ans.—The heat is not sufficient to destroy parasitic ova; but few or no cases have been received of infection from this source.

MR. EDITOR.—Will you or some reader kindly state the name and address of one or more veterinary colleges, and the term of study required for graduation?

California. C. M.

Ans.—The leading veterinary college in the United States is the American Veterinary College, 141 West 54th St, New York city.

MARRIAGES.

BASSETT—HALLOWELL.—At Friends' Meeting House, Fifteenth and Race, on the 23d instant, Dr. Franklin L. Bassett, of Philadelphia, and Anna E. Hallowell, daughter of the late John Edgar Hallowell, of Sandy Spring, Maryland.

CARMAN—HORTON.—In White Plains, N. Y., March 9th, 1881, by the Rev. O. Haviland, assisted by Rev. J. M. King, D.D., Albro R. Carman, M.D., of New York, and Gertie, daughter of Mr Thomas Horton, of White Plains, N. Y.

LAVERTY—FREY.—On Feb. 3d, 1881, at St. Paul's Lutheran Church, York, Pa., by the Rev. L. A. Gotwald, D.D., DeWitt C. Laverty, M.D., of Middletown, Pa., and Bertha, eldest daughter of George S. Frey, of York, Pa.

SIMMONS—SHIBLEY.—At Rural Grove, Mass., at the residence of the bride's parents, March 2d, by the Rev. G. C. Simmons, assisted by the Rev. E. D. Hammond, Herbert M. Simmons, M.D., of Cœymans, and Miss Hattie Shibley, of Rural Grove.

DEATHS.

MONELL.—On the evening of March 7th Dr. Joseph S. Monell, at Green Cove Springs, Florida.

SELTZER.—On the 23d instant, Dr. John H. Seltzer, in the thirty-sixth year of his age.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1215-126 7eow ROBERT SHOEMAKER & CO.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

Lecture.

THE PATHOLOGY OF ALBUMINURIA.

Delivered at the Paris Faculty of Medicine,

BY M. CHARCOT,

Prof. of Pathological Anatomy.

Translated for the Medical and Surgical Reporter.

Gentlemen:—At our last lecture I briefly enumerated the conditions, normal or pathologic, under which albumen is found to be present in the urine; and in alluding to the temporary albuminuria sometimes observed in normal conditions of the system, a subject which has attracted particular attention on the part of physiologists during late years, I recalled to you the observations of M. Leube and Edlefsen regarding the transitory albuminuria observed in overfatigued soldiers.

This variety of albuminuria present in the normal condition was also brought into notice by Prof. Semmola, of Naples, who observed it in stevedores, miners, etc.

The fact is sufficiently interesting not to be lost to view. I then endeavored to establish a parallel between the varieties of albumen found in the blood and those found in the urine in albuminuria. The conclusion arrived at from this comparison you have not forgotten; it is that all the varieties of albumen isolated by means of chemical analysis from the urine of patients in albuminuria are found with the same chemical and physical characters in the serum of normally constituted blood. This important fact renders the following proposition very probable, with a few very rare exceptions: *all the varieties of albumen found in the urine, and which necessarily originate from the blood, are in reality nothing more than the different forms of albumen found in this fluid in the normal state;* and the kidney which eliminates them induces no appreciable physico-chemical modification in their structure.

We shall see to what point this proposition, founded on physico-chemical condition, is justified by physiological and chemical facts. The first question which presents itself for solution is the following: In what part of the urinary apparatus takes place the secretion of the diverse varieties of albumen found in the urine? According to the most recent works this secretion is effected in the glomerules, to the exclusion of the tubuli contorti (canaux du labyrinthe).

I brought to your notice, the other day, the fact that, contrary to what happens for the albumen of the blood serum, that of white of egg, which is, for that matter, totally foreign to the constitution of the blood, passes in the urine, when ingested in sufficient quantity or when injected into the veins of an animal. This is not, properly speaking, a pathological fact, for these animals do not suffer, nor does the human subject, from this albuminuria provoked experimentally.

I recall to your memory that in such a case the albumen of white of egg may be recognized as such in the urine, because it retains in this fluid its proper physico-chemical characters, which distinguish it from the albumen of the serum. It is then necessary to determine if this albumen of the egg, eliminated from the blood, passes in effect, as we have declared, by the glomerules.

Here is an experiment, due to M. Nussbaum, which demonstrates such to be the case. If a certain quantity of white of egg is injected into the general circulation in the frog, it passes in the urine, just as in the mammifer. But if the renal artery be tied previous to the injection, under these new conditions albumen no longer passes.

But it may be proved that at this moment the epithelium of the tubuli enjoys all its vital properties, for if an intravenous injection of a solution of urea be made in this animal with the emulgent artery tied, this substance excreted by the tubuli carries off with it a certain proportion of water. So that, notwithstanding the suppression of the functional activity of the glomeruli, urea injected into the general circulation may be found in the bladder.

What has been said of white of egg may be said also of the peptones, which also, according to M. Nussbaum, pass in the urine in the normal condition in the frog and are s creted by the glomerule.

The same experiment of M. Nussbaum slightly modified may be applied to the solution of another problem. That is, when it is no longer the white of egg but the albumen of the blood serum which passes in the urine, that is, when we have the conditions of common albuminuria in the human subject.

You have not forgotten the famous experiment of Overbeck, the temporary ligation of the renal artery. When the ligature has been left but a few minutes in place, the urinary secretion, at first suppressed, reappears after one-half or three quarters of an hour, when the ligature has been removed. The first urine which passes is scanty and albuminous. It is evident that this albumen originates from the blood, and it is necessary to seek in what part of the kidney this filtration takes place. This question also may be resolved by experimentation on the frog.

After ligating the renal artery, a certain quantity of urea is injected into the blood, which passes naturally by the bladder. But if the ligature be removed for the next four or five hours, the urine will contain albumen with the urea.

Contrary to what happens in mammifers, it is possible, in the frog, to determine with precision the point where the secretion of albumen takes place; and to demonstrate that this secretion is effected in the glomerule, without participation of the tubuli contorti, which, nevertheless perform their usual function in eliminating urea, notwithstanding the ligation of the artery.

We will, gentlemen, in human pathology, meet with more than one example serving to show this independence, which, in albuminuria, may exist between the performance of the functions of the glomeruli and those of the canaliculi contorti. As example of this independence of action, might be cited that form of albuminuria which might be styled cardiac albuminuria, and which supervenes when, through grave trouble in the action of the heart (asystole) pressure becomes lowered in the arterial system while it is, at least relatively, increased in the venous system. Under such conditions the urine is scanty, dark colored, having a specific gravity of 1.035 to 1.040 (consequently above the normal standard), and contains a certain proportion of albumen.

But the important fact is, that when the urine of twenty-four hours is collected, it is found that the proportion of urea and uric acid is at least at the normal standard. Thus, while the glomeruli perform their functions badly, and furnish the liquid constituents of the urine in but small proportion, although allowing the filtration of albumen, the tubuli perform their functions separately and eliminate urea and uric acid in the usual proportions.

Take notice that this last point is perfectly in conformity with the teachings of pathological anatomy in such a case. It is in effect perfectly established that in the primary phases of the development of albuminuria, when, however, the urine has long contained a certain proportion of albumen, the epithelial cells of the tubuli contorti do not present any apparent morphologic modification.

II. But for the present we will leave aside the consideration of cardiac albuminuria; we can return to it later. We will now take up the results of experiment.

The experiments of M. Nussbaum have one great disadvantage; they were made on the frog, and it may always be objected that they are not applicable to the human subject. I shall give you a summary of the results obtained by a method differing from that put in practice by M. Nussbaum. These results, less decisive than the preceding, offer, nevertheless, a special interest, for they concern the superior animals. I allude to the recent and almost simultaneous experiments of MM. Ribbert, Posner, and Litten, which are absolutely concordant.

When the experiment of Overbeck, the temporary ligation of the renal artery, is performed on the dog or rabbit, albuminuria is produced under the conditions with which you are acquainted.

If the kidney of an animal submitted to such

an experiment be suddenly torn from the abdomen and thrown immediately into boiling water, it is evident that the albumen at that moment traversing the kidney undergoes sudden coagulation, and is fixed in the point where it is secreted; and, in fact, it is found that the capsule of the glomerule, which, under normal conditions, is applied closely over the Malpighian body or tuft, is in this case separated therefrom by an amorphous, transparent, granular mass, which distends the capsule. This substance presents all the characters of albumen in the coagulated state.

At the same time it is found, particularly when the ligature has been long maintained in place, that the epithelium of the glomerule has undergone all the modifications described by Langhans, and which this author considers as characterizing acute inflammation (thickening in the vicinity of the nucleus of the protoplasm of the cell, which in this case becomes permanent and forms an elevation in the cavity of the glomerule). Without doubt, a certain quantity of this amorphous material is always met with in the tubuli, but as the epithelium here is intact, there is every reason to suppose that it is by the glomerule the albumen first filtrated, and that it subsequently passed into the tubuli.

The same observations have been made in cases of albuminuria, artificially produced in animals, by injection of white of egg. In such cases it is also found that the albumen is secreted by the glomerule and not by the tubuli. Of course, it must be understood that counter experiments have been made, proving that in the normal state in men and animals, when there is no albuminuria, this coagulum is never found in the capsule.

This is, it must be remarked, a fact of primary importance, because it overthrows definitively the theory proposed by M. Wittich and Küss. You know that, according to these authors, in the conditions of normal secretion the urine filtrated by the glomerule carries with it all the constituents of the blood-plasma, including albumen. But this albumen never appears in the urine, for it is taken up as it traverses the canaliculi by the epithelium which lines them.

I return to this theory, and insist on the criticisms made regarding it; for it has been applied by many authors to the interpretation of pathologic phenomena.

Albuminuria, according to certain theories we have mentioned, is almost always the result of a material alteration of the epithelial cells of the tubuli; and as can be readily understood, these altered cells become incapable of performing their functions, and permit the passage of the albumen secreted in the glomeruli, which consequently appears in the urine.

This theory is ingenious but is contradicted by many facts; and through this circumstance particularly, that in the normal state the anatomic method does not reveal the presence of albumen in the glomerule.

It results, gentlemen, from these same observations of MM. Ribbert, Posner and Litten, that in all pathological cases where albuminuria is present in man, whether transitory or durable, functional or accompanied by profound lesions of the kidneys, albumen has always been found in the cavity of a certain number of capsules.

The researches made recently by MM. Browicz and Cornil, on the alterations of the kidneys in animals poisoned by cantharides, may be considered in connection with the preceding observations.

In such a case there is acute inflammation, and the albumen which passes in the urine is accompanied by elements (leucocytes and hematies) which demonstrate the nature of the pathologic processes.

If the kidney is examined forty minutes only after the subcutaneous injection of cantharides, an albuminous exudation is already found in the cavity of the glomerule; and there is every reason to believe, after mature consideration of the facts, that it is at this point, that is in the glomerule, that this exudation takes place, appearing only secondarily in the tubuli.

Thus, gentlemen, as you see, in taking as basis the documents I have brought before you, we are led to establish in principle that it is always by way of the glomerule, and without participation on the part of the tubuli, that albumen is eliminated.

III. Fortified with the knowledge of the anatomical, physiological and pathological facts which we have collected in preceding studies, we can now take up, with some chance of arriving at a conclusion, a question which is difficult, complicated and obscure, viz.: the pathogenesis or pathological conditions which induce albuminuria. The pathological conditions invoked by different authors to explain the passage of albumen in the urine may be, although numerous, considered under three principal headings:—

1. First it is said there is a primary alteration in the blood itself, of which albuminuria would be the immediate sequence. 2. Sometimes there is trouble in the general circulation or in that of the kidney. 3. There may be some direct ana-

tomical alteration in the epithelial elements of the renal gland.

To each of these groups corresponds a theory; certain eclectic authors, admitting the validity of all three, apply now one, now the other, according to the case, to the interpretation of the facts. But others, more exclusive, admit but one of these systems, and apply it to all cases. We will consider, one after the other, these diverse theories, and seek to determine up to what point they conform to the physiological facts we have been considering.

The first theory which presents itself is that of *hematogenous albuminuria.*

It was thus designated by M. Stokvis, in an important memoir entitled "Experimental Researches on the Pathogenetic Conditions of Albuminuria." (*Journal de Méd. de Bruxelles*, 1867, vol. 44.) Unfortunately, I have but the time to mention the essential conclusion at which he arrives.

In this system of hematogenous albuminuria there is supposed to exist primarily an alteration of the blood, of which albuminuria is the immediate consequence. The existence of an alteration of the blood, consisting in the presence of an excessive quantity of water in this liquid (hydræmia, hypo-albuminose) was often invoked as a cause of albuminuria, particularly about twenty years since.

Certain very old experiments of Magendie, repeated by Mosler, were much relied on at this period. These experiments consisted in injecting into the blood of animals a certain quantity of water; almost always the urine of these animals became albuminous. The fact is so, but it received an erroneous interpretation.

The albuminous urine of these animals is tinged red; it contains blood globules generally, or at least the coloring principle of the blood, that is hæmoglobin. Two things may happen in these experiments, made in a very summary manner by the first observers: 1. A considerable quantity of water was injected and with rapidity. In such cases there was a sudden elevation in the arterial tension. Some of the vessels of the kidney suddenly distended, ruptured and allowed the blood to escape, thus provoking albuminuria.

2. Or the injection was made slowly, though in large quantity. In this case the globules become altered by the action of the water, and permit the escape of the hæmoglobin which was mixed with the serum. Or, this hæmoglobin is an albuminoid principle, which filtrates through the membranes with as much facility as the albumen of the egg. It is then nothing astonishing to have it pass in the urine subsequent to the dissolution of the red globules. When such is the case, it is not, properly speaking, albuminuria, but hæmatinuria, as Vogel called it; or, better, hæmoglobinuria, as it is styled at present. The urine in such a case is diversely colored; sometimes of a bright red tinge, it may be dark red or almost black. Coagulation is induced by heat and nitric acid, as when albumen of egg is present, but the precipitate is not dissolved by an excess of acid.

Hæmoglobin is, by this character, already distinguishable from ordinary albumen. Added to this, spectral analysis reveals in such urine the band peculiar to hæmoglobin.

In these experiments of injection of water, followed by hæmoglobinuria, the dilution of the blood is carried very far; and this liquid presents itself under conditions never observed in the human subject.

On the other hand, if in the animal water is injected in small quantity, in small proportions at a time, and with precaution, the urine never, according to the experiments of Stokvis and Westphal, contains either albumen or hæmoglobin.

It is very probable, then, that albuminuria, or better, hæmoglobinuria, through dilution of the blood, does not occur in the human subject; but I would say in passing, that it is frequently induced in man by other pathological conditions; thus in grave fevers, with a typhoid state of the system, with putridity, as the older physicians termed it; in dothienenteritis, scarlatina, pernicious jaundice, or again, in poisoning by sulphydric acid or arseniuretted hydrogen.

The study of hæmoglobinuria, long neglected, has been taken up again recently, particularly in Germany, and during the last ten years the medical journals frequently contain cases of this kind.

Communications.

ON THE USE OF THE OBSTETRICAL FORCEPS.

BY T. C. WALLACE, M.D.,

Of Cambridge, N. Y.

A paper read before The Union Medical Association, at Eagle Bridge, N. Y.

(*Continued from page* 376.)

Let us look further. Every author I have named impresses upon us the importance, the imperative necessity, of supporting the perineum. Prof. Goodell strenuously urges us to leave the perineum unsupported, and quotes some of

the most eminent authors in France and Germany in support of this advice. In England, he says, West, Swayne, Graily Hewitt, Taylor, and Thompson, have long since discarded support to the perineum, as not only useless, but *positively injurious.* Prof. Taylor, of Bellevue, declares "that support to the perineum is unnecessary, and that as many lacerations occur in the practice of those who render support as in those who do not." Not only are we enjoined by eminent authorities carefully to support the perineum, and by others of equal eminence to let it alone, but of those who order its support, each has a different method. One advises a folded napkin to be applied by the hand. Another teaches this is nonsense, and that we must use the bare hand; still another directs us to hook a finger in the anus and pull the perineum forward. One insists that, on the score of delicacy, we must always scrupulously keep our patient covered with a sheet, forbidding us even to go the traditional "one eye on it." Another directs that the perineum be freely and fully exposed to view that the eye may detect the first symptom of laceration.

It is often asked, "When doctors disagree, who shall decide?" When our authorities thus disagree, how shall the doctors decide? I answer, each for himself, guided by the dictates of common sense and his own best judgment. For the benefit of those who dare do nothing that is not explicitly sanctioned by some authority, I propose to support any statement I may make, or any advice I may offer, by equally as good authorities as any I have named and rejected. I assert that whenever, in a vertex presentation, with no deformity of the pelvis existing, with the os uteri dilated, or *easily dilatable*, the head does not advance in proportion to the force of the pain, or the longer continuance of the labor endangers either the mother or child, or involves a long continuance of suffering to the mother, the time has arrived to resort to the forceps. Further, that its use is often proper to do away with the nervous excitement of the patient, and to relieve the harrowing anxiety of her friends; and still further, that its application is many times justifiable to save the time of the practitioner; for I can see no good reason why we should spend hours by the bedside of the parturient, to the detriment of other patients who urgently need our services, when it requires but the touch of skin to complete the labor. This may seem a bold assertion, but it is my opinion, on which I have acted for years, and with no cause for regret. I cannot agree with Meigs, that violent pains and extreme resistance contra-indicate the use of the forceps. They are even an indication for its use. If extra force is needed the arm of the practitioner can furnish it more cheaply than the womb of the woman. I must differ from Churchill, for I cannot think it my duty to sit idly by the bedside and suffer a woman to travail for hours, even if I am "fully satisfied" that nature will ultimately triumph.

With equal reason might I decline to give exit to suppuration with my bistoury, and thus relieve excruciating pain, provided I was "fully satisfied" that in time the pus would safely find its way to the surface. As to the rules given by Ramsbotham, and others, that we must suffer the woman to become febrile, or allow impaction to exist for a certain number of hours before we interfere, I utterly and totally repudiate them. In my opinion any practitioner who would be governed by such absurd rules had better cease feeling for the child's ears and direct his *tactus eruditus* to examining his own.

Hodge, in his quarto on obstetrics, after advising early resort to the forceps, says, "In giving this advice we will doubtless fall under the censure of those who direct their anathemas upon what they call meddlesome midwifery, which expression, although it may answer as a cause to the ignorant and rash, the author has always regarded as evidence that those who use it are ignorant alike of the resources of nature and those of science, and hence, trusting to nature until the dangers to the child and parent are so cumulative that artificial assistance is not only unavailing, but often accessory to a fatal termination. He who understands accurately the natural modes of delivering, and the resources of his science, may often enjoy the unspeakable pleasure of diminishing corporeal and mental suffering in many cases which might possibly, after much delay, have terminated without assistance, and very often of preserving lives which would otherwise have been sacrificed."

Regarding the dangers attributed to the forceps, I not only deny their existence, but assert that its judicious and early use is the surest way of arresting danger. As to its use causing fracture of the pelvic bones, separation of the symphysis, etc, I confidently state it would be impossible to produce such results. Equally impossible would it be to thrust a blade through the uterus or vagina. In Bedford's case of complete occlusion of the meatus urinarius, with vesico-vaginal fistula, etc., the injury doubtless resulted from the length of time the woman was in labor (three days) before delivery was effected. She

would have been all right had it not been for the delay. The trouble was not that the forceps was *used*, but because it was *not* used. The forceps is, indeed, a peculiarly innocent instrument; with its curved form and rounded edges it is almost incapable of mischief. It cannot cut, fracture, tear or scrape. Neither can it bruise the soft parts without the most stupid ignorance or criminal violence. Perineal lacerations are, in some cases of labor, unavoidable, but I do not consider them more apt, indeed not so apt, to occur in forceps delivery than in unaided labor. Most lacerations occur where with one supreme effort the head is suddenly ejected. With the forceps we have a more perfect control of the head, and by retarding its passage at such times, and especially by keeping it pressed closely against the pubes, we may often avert laceration. I am satisfied I have many times thus prevented threatened laceration. Hodge says, "A very large proportion of vesico-vaginal fistulæ met with result not from the *use* but from the *neglect* of the forceps." This observation is confirmed by the fact that few practitioners ever apply the forceps directly toward the bladder or rectum, but somewhere on the sides of the pelvis. Dr. Burns, of Glasgow, says, "it is erroneous to consider the forceps a painful or dangerous instrument, as it was for many years used clandestinely, and *without the knowledge of the patient.*" He says in cases of impacted head it is better to interfere too soon rather than to procrastinate, and he is supported in this advice by Hamilton, of Edinburgh, and Osiander, of Göttingen. Dr. Reeve, in a review in the *American Journal of the Medical Sciences*, says, in regard to the serious objection to operative interference with labor, that lesions may be produced by the unskillful use of instruments. We shall borrow Dr. Thorburn's reply, that we have no more right to debar the suffering woman from the advantages to be derived from the use of instruments, on the ground that they may be clumsily employed, than the surgeon has to counsel the utmost delay in hernia, because a bungler might wound the bowel.

But the truth is, authority is almost unanimous that it is the prolonged pressure of the child's head which produces sloughing of the maternal tissues and fistulæ, and *not* the use of instruments. This has been shown by Simpson, Beatty, Hodge, and numerous others. We may add to their testimony that of Baker Brown, who, before the British Medical Association, said, that of one hundred cases of lesion following labor, ninety per cent. were attributable to protracted labor. The idea that they were produced by the use of instruments is a farce and a bugbear. Joulin states that he availed himself of the ample experience of Jobert, for the solution of this question, and had access to an unedited manuscript containing the statistics of one hundred and fifty cases; the opinion of that eminent surgeon was, decidedly, that fistulæ are always the consequence of prolonged labor, and *never* result from the application of the forceps. In our country, out of two hundred and fifty cases given by Dr. Emmett, not more than three cases resulted from instrumental delivery, and these were cases of malpractice, and of no statistical value; all the rest were from prolonged labor. Now, if there be a question in medicine which may be considered settled, it surely is this. It was only reconsidered in this article because of the pertinacity with which the objection is advanced by those who are opposed to operative interference with labor, except as a dire necessity. Regarding danger to the child, Meigs says, "I think it almost out of the bounds of possibility to injure the fœtus with it, provided it be well adjusted and used with common discretion." Dr. Reeve, in the paper before quoted, says, "As the forceps has been neglected the use of the perforator has increased." This surely is a pregnant fact and should be admitted into the pleadings. Thus we have the well known table given by Simpson, which goes from Siebold, with one forceps delivery to every seven cases, and one craniotomy in 2093, to Collins, with one forceps delivery in 617 cases, and one craniotomy in 141. Collins carried reliance on nature to the extreme, and the results are patent. Yet this table does not give truly the other end of the scale. Fr. B. Osiander, during thirty years' administration of the Göttingen Lying-in Asylum, used the forceps in every $2\frac{5}{10}$ cases; *yet he only used the perforator once in his life!*

Regarding the proper application of the instrument, the great majority of French, English, and American authors teach that the blades are invariably applied to the sides of the head. In my opinion, these teachings are wrong in theory, productive of evil consequences in practice, and often impossible of execution. The grand question in the use of the instrument is, whether its introduction shall be governed by the position of the head or by the shape of the obstetrical canal. Whether we shall consider the anatomy of the child, or the anatomy of the mother. Whether we shall regard the field in which our operation is to be performed, peculiar and determined in its shape, or pay attention solely to the position in which the object to be grasped happens to lie.

In my opinion, the blades should invariably be applied to the sides of the pelvis; their pelvic curve in accord with the curve of the pelvic canal; that the position of the head is not of the least importance, and cannot be advantageously, or in many cases, even innocently regarded. For what purpose is the pelvic curve given to the forceps? It is only a single direction this curve can fit, and it is impossible to accommodate it to any other direction. When an author directs us to place the forceps antero-posteriorly at the superior strait (as must be done if the blades are applied to the sides of the head), he directs us to execute an impossibility. In this advice to regard only the pelvis and disregard the position of the head, I am supported by many German authors, by Barnes, of London, and by Byford, of this country. Barnes says, "the position of the head may be disregarded. The pelvic curve of the blades indicates that these must be adapted to the curve of the sacrum, in order to reach the brim. They must, therefore, be passed in the transverse diameter of the pelvis; one blade will be in each ilium, and the head, *whatever its position to the pelvic* diameters, will be grasped between them." The universal force of this rule much simplifies and facilitates the use of the instrument.

Not only does it apply to the position of the head in relation to the pelvic diameters, but also to all stages of progress of the head, from that where it lies above the brim down to its passage at the outlet. Governed by the usual rules, I used the forceps but three times in the first ten years of my practice. A German physician then instructed me in this better way. Since then I have used it with increased frequency. I find that for the past five years of my practice I have used it in thirty per cent. of all the labors I have attended. During this twenty years, I have never done harm to any child nor inflicted injury upon any mother. I have never attended a woman in labor whom I have previously delivered with this instrument, but that she would not only ask, but earnestly entreat its use. Of the fifty-one and more different forceps which shall we select? I think there is little choice between them. Any one of them is good enough. It is about with them as it is with the many different mowing machines; every farmer thinks the one he has the best of all.

The only one I have ever owned is Davis's, and I am perfectly satisfied with it. I like it for the marked boldness of its pelvic curve, and because of its English lock.

I prefer that the patient lie on her back; the pelvis is then firmly fixed upon the bed, the operator has free access to and perfect control of his patient. If the head lays high in the pelvis, her hips should be brought completely to the edge of the bed, the thighs abducted and her feet supported by assistants. When the head is at the inferior strait this is unnecessary. Introduce first that blade which (when both are in position) will lie nearest the sacrum of the mother. It is the blade which the operator will take in his left hand and which will lie in the left side of the pelvis. With one or two fingers of the right hand, let the operator touch the head well back toward the maternal sacrum, taking this blade in his left hand, holding its handle obliquely over the right groin of the mother, he introduces its tips into the vulva and slides it along the vagina, guided by the fingers of his right, until it is engaged between the head and the maternal parts. As the point of the blade passes beyond the reach of his fingers, he must rely upon his anatomical knowledge for its further guidance. He must mentally see the head simply as an ovoid body lying in the obstetrical canal, and considering that it makes no difference in what diameters it is grasped, his whole aim must be to keep his blades against the sides of the pelvis. While gently sending his blade along he must bear in mind the curve of the utero-vaginal canal, and also the convexity of the fœtal head, and remember that his blade has both a pelvic and a cranial curve. While his blade follows the curve of the pelvis, it must follow it so exactly that the sides of the blade will be at the side of the pelvis, and its concave edge will lie behind the pubic bone. By rapidly (but not too rapidly) depressing the handle until it is brought into the mesial line, this double movement is readily accomplished. The other blade is now taken in the right hand, and similarly introduced. The application of the forceps in this way, so far from being a difficult matter, is exceedingly simple and easy. The blades glide into their proper places almost as if instinct with intelligence.

Introducing the instrument for the first time, one will perhaps be surprised at the depth to which it will penetrate, and may fear he has introduced it too far. This is impossible. The forceps should completely enclose the head; after passing the head its further progress will be arrested by the body of the child. Much difficulty is often experienced in working the forceps. Many and confusing directions are given by authors for effecting this purpose. Meigs says perhaps we can push a blade forward

or backward. Some recommend us to withdraw the blades and try again. Some to remove one blade and endeavor to use the other as a vectis, and perhaps a pain may force the head down enough, so that next time the blades will lock. But what if it shouldn't? Bedford says we shall often succeed by "judicious manipulation," which is truly explicit. In fact, the whole thing, as laid down in most of our text-books, is a sort of trusting-to-luck affair. None of these authors recommend the puzzled operator to *swear*. But neither do they forbid him from so doing. If any one thus situated should swear, let him direct his anathemas, not against the innocent blades, they are all right, but rather let him vent his expletives against his venerated authorities, who have given him such a plentiful lack of instruction in this, his dilemma.

Now I will give a simple and certain rule for locking the forceps, which will always succeed. Send the blades well home; push them along as far as they will go, as already explained; there must be no fear of introducing them too far; then crowd the handles well back against the perineum. The instrument is now fairly grasping the child's head, the axis of its pelvic curve accords with the curve of the pelvic canal, the blades lie at the sides of the pelvis, parallel to and symmetrical with each other, the handles drop on the same plane, and by approximating them they will necessarily lock.

We are given extreme caution against letting our forceps slip. Meigs directs that one finger be kept in approximation to the head, to detect the first sign of slipping. This caution is unnecessary. My forceps never have slipped, nor is it possible for a good instrument properly applied to slip off. A little reflection will convince any one that this assertion is correct. With the blades enclosing the head, as they should do, nearly or quite to the cervical region, for their tips to override the convexity of the cranium involves their separation for at least two inches; this necessitates an equal separation of the bulge of the blades, but these are against the sides of the pelvis and they cannot separate.

That forceps do slip I admit, but it is because the tip of the blade is not pushed beyond the bulge of the cranium. The instrument slips off, because it was never fairly put on. Shall we use our forceps as compressors, as levers, or as tractors? All authors teach that in this operation we should imitate nature as closely as possible, and yet many of them tell us to use our instruments as levers, by moving the handles from side to side. Bedford, expressly directs that the force be one-third extractive and two-thirds lateral. Is this an imitation of nature? Does nature expel a child in that zig-zag, see-saw manner? The true use of the forceps is as *tractors*. Compression should be exerted only so far as is necessary to fix the instrument firmly upon the head, so as to prevent any motion of the blades upon the scalp. The blades and the head must be, in fact, as one body; their movements must be simultaneous. The compressing force necessarily used in grasping the handles when extracting is all that is allowable. Traction must be made in accordance with the axis of the pelvic canal. During extraction let there be neither excitement nor hurry on the part of the operator. In imitation of nature let him have periods of rest as well as of action. If the pains are frequent enough, let him act in conjunction with the pains. If not frequent enough, he has them at his command, for as soon as he makes traction the uterus will promptly respond with a pain.

Gentlemen: The advice I have offered as to when we should resort to our forceps; the statements I have made as to its safety, and the directions I have given for its application and use, although directly at variance with the teachings of many eminent authors, are not only supported by authors of equal eminence, but what is far more to me, are sanctioned by my own judgment and confirmed by years of practical experience, and I earnestly hope they may commend themselves to your thoughtful consideration. Let me ask, as a favor to yourselves, that you give this subject earnest thought and practical applications. By so doing you will save for yourselves many an hour of precious time, spare your waiting patients many an anxious thought, rescue many a child that would otherwise perish, relieve many a woman from hours of unspeakable agony, and be afterwards the recipient of her heartfelt gratitude. If, by the hearing of this paper, any one who has hitherto looked upon the forceps with disfavor shall be induced to alter that opinion; any one who has previously regarded it as dangerous, shall hereafter consider it a safe and beneficent instrument; any one who has formerly dreaded its introduction as difficult, will now think its application simple and easy; in fine, if it shall in any degree tend to promote the more frequent use of this most valuable instrument, my object in writing it shall have been accomplished.

—Cider has been declared an intoxicating beverage, by the Connecticut legislature.

MEDICATED GELATINE IN THE TREATMENT OF NASAL CATARRH.

Read before the Philadelphia Laryngological Society,

BY DR. ISAAC BARTON,

Chief of the Throat Department, Jefferson College Hospital.

By this I mean the use of the so-called nasal bougie, which consists of a piece of moulded gelatine, about two or three inches in length, having a piece of string running through its entire length, and having a free quantity for the purpose of security. For use, the bougie is to be slightly coated with sweet oil, and gradually inserted by rotation, into either side of the anterior nares. It may then be secured by tying the free quantity of string around the ear, or fastening the string to the cheek by a small piece of adhesive plaster. The head of the patient is then to be inclined backward, and as the gelatine dissolves and flows from the posterior nares into the throat the patient may expectorate at pleasure.

These bougies dissolve in from ten to fifteen minutes.

The following are the medications I have used, which were made for me by Mr. C. L. Mitchell:—

No. 1.	Liq. iod. comp.,	♏v
2.	" " "	♏x
3.	Morph. sulph.,	gr. ¼
4.	Zinci sulph.,	gr. ij
5.	Zinci sulph.,	gr. ij
	Acid carbolic,	gr. ss
6.	Ext. krameria, fld.,	gr. viij
7.	Zinci sulph.,	gr. ij
	Acid carbolic,	gr. ss
	Ext. hydrastis, fld.,	gr. v
8.	Iodoform,	gr. ij
9.	Liq. iod. comp.,	♏x
	Acid carbolic,	gr. j
10.	Salicylic acid,	gr. j.

From all these medications I have received the best results from Nos. seven, nine and ten.

J. K., aged 23 years, applied to me, complaining for nearly eight months of a discharge from the back portion of the nostrils into the throat, which discharge was of a thin, mucilaginous character; his general health good; no specific history; sometimes suffered with slight headache. An examination revealed the nares to be moderately filled with mucus. I washed out the nares with Thudichum's nasal douche, after which I inserted two bougies (one into each side of the anterior nares) medicated with zinci sulph., gr. ij, carbolic acid, gr. ss, and ext. hydrastis, fld., ♏v. These dissolved in fifteen minutes. I made this man come to me three times a week, and inserted these bougies after his using the douche, on the same day. At the end of three weeks there was no discharge and had been no headache.

I have used these bougies with some good results in cases of ulceration of the nasal septum.

Clara G., aged 26 years, applied to me, complaining of great pain on left side of nose, which she had had for four or five days. On examination I found a somewhat superficial ulcer, about the size of a three-cent piece, on the left side of the septum. This I carefully cleaned with absorbent cotton, and inserted a bougie containing ¼ gr. morph. sulph., which dissolved in twenty minutes. I used one of the same kind on the next day, after which she had no pain. On the third day I used one medicated with two grains of iodoform (which takes half an hour to dissolve), and continued the use of the same daily, for a week, after which time the ulcer had healed very nicely, the patient having no pain or difficulty in breathing through the nostrils.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WM. PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by WM. H. MORRISON, M.D.

A Case of Widespread Syphilitic Disease, with Cystic Degeneration of the Pancreas, Numerous Pancreatic Calculi, Atheroma of the Aortic Valves and Arteries, Obstruction of the Bile Ducts, Distention of the Gall Bladder, Jaundice and Diabetes. Death. Autopsy.

GENTLEMEN—The patient now before us presents an extremely interesting and important condition. I shall first study those conditions which are rapidly passing away.

He is 61 years of age, a resident of this city. He has been a wholesale liquor dealer. Lately he has been a clerk. He has never been very intemperate, and says that he has never had any venereal trouble. He has had, however, a rather hard life, on account of business anxieties. For the past two years he has been in ill health. At first he was subject to constipation, which was followed by diarrhœa. The stools were light in color. He began to lose strength and to be subject to dyspeptic symptoms. Next, he had pain over the liver, and pain extending to the shoulder. Nine months ago he gradually became jaundiced, The color grew deeper and deeper, until it was quite dark; much darker than it now is. Eight months ago he noticed a lump under the ribs on the right side. He has lost forty pounds of flesh lately.

The jaundice is very marked in the conjunctiva. He has also well-marked arcus senilis. The jaundice extends over the whole body. We usually find it best marked where the skin is thin and soft, as over the stomach.

Looking at the abdomen, we see a little swelling on the right side. I grasp it and find that it is rounded; that it extends upward until I come to a ridge, which I find passes under the ribs. This is the edge of the liver. This mass is continuous, then, with the liver, which is much enlarged, and extends two inches below the border of the ribs. Passing around the lump, I again come to the edge of the liver; I also find a round swelling at the left lobe. What is this lump at the right side of the liver? It is the distended gall bladder. I find that it yields a little on pressure. It is just in the position of the gall bladder. It has the shape of the gall bladder; it can be traced up into the liver on both sides. This is sufficient to prove that it is the gall bladder very much enlarged, and evidently distended with bile. We have here a very remarkable condition: enlargement of the liver, a suspicion of growth in the left lobe, and great enlargement of the gall bladder.

In jaundice we have a failure of the bile to follow its proper course, and the bile pigment accumulates in the blood. From the blood it escapes into all the secretions and every tissue of the body, the brain and its membranes, the solid viscera and the bones. The jaundice is most marked in the parts which are usually whitest. It also stains the tears, milk and sweat; but perhaps the fluid in which the color is most marked is the urine. The healthy color of the urine changes to a brandy color, so dark sometimes as to be entirely opaque. A week ago this man's urine was a dark brandy color, almost the color of porter; now we find that it is only tinged with bile. The tests for the coloring matter of the bile are very simple. In the first place, if you shake the bottle and have a yellow color froth, that is sufficient. If we take a test tube and place some of the urine in it, and then allow a little fuming nitric acid to pass down the side, there will be a beautiful play of colors. In this case there is a very faint trace of green. If we place some urine on a plate and add a drop of the acid, we shall have the same effect produced.

There is another question connected with this subject. The bile consists of something besides coloring matter. It contains a number of organic compounds, the most important of which are glycocholic and taurocholic acids, in combination with potash and soda. These naturally pass from the body through the bowels; but when the exit of the bile is prevented these salts must accumulate in the blood. We would naturally expect to find them in the urine under these circumstances. The way to obtain them is to take a certain quantity of urine, evaporate to dryness, treat the residue with a large excess of alcohol, because the salts are soluble in alcohol, filter, and add an excess of ether, which precipitates the salts; then filter and dissolve in water, and purify by filtering through animal charcoal. We then add sugar and sulphuric acid, and if the bile salts are present there will be produced a cherry red color. This man's urine has been tested a number of times for these salts, but they have not been found. This process is unreliable and not of much clinical value.

I have seen cases where no bile salts could be detected in the urine, yet post-mortem examination proved that no bile could have escaped by the bowels for weeks. The presence of the salts in the urine is of value, but their absence does not disprove obstruction.

There is no albumen in this urine Its specific gravity is 1.010. It is less than the normal, which is 1.016. I will now test it for sugar. You will find, when we come to study diabetes, that there is a very important connection between diseases of the liver and diabetes. I never treat a case of hepatic without examining the urine for sugar. I use Fehling's solution, and find that there is present a considerable amount of sugar. The stools in jaundice become very pale, sometimes of a putty color. It is very unusual to find so small a quantity of biliary coloring matter in the urine with stools as light in color as this man's are.

Sept. 23. We shall now study this case carefully. We have found in this case a man overworked and run down with enlargement of the liver; deeply jaundiced; with immense enlargement of the gall bladder; with urine that is bile stained and containing sugar, although, remarkably enough, its specific gravity is only 1.0.0—below normal. Now, let us study this case, and endeavor to understand it fully.

I did not call attention before to the œdema of his lower extremities. They pit upon pressure as high as the knee. There was no albumen in the urine. We have found no reason to suspect disease of the kidney. Although there has been no fever, the action of the pulse has not been normal. The arteries are found to be very hard and atheromatous. The pulse is rather small and frequent. Examination of the heart shows obstruction of the aortic orifice. There is a systolic aortic murmur, with its maximum intensity at mid-sternum, and transmitted into the arteries of the neck. We find, in this case, very widespread disease of many organs. We have here atheroma of the arteries, fatty degeneration of the cornea, lesion of the aortic valve, enlargement of the liver, obstruction of the biliary duct, diabetes, and dropsy. There must be some very deep cause to explain all this.

First, in regard to the condition of the liver, I told you that I found in the epigastrium an irregular enlargement in the position of the left lobe of the liver. As I press my fingers deeply in at this region, I feel a round, irregular mass. It feels like enlarged glands; as though the glands in the fissure of the liver were enlarged.

What condition of the liver is present? We would at once think of cancer. Here we have a disease, coming on without apparent cause, inducing jaundice, which deepens and becomes persistent, and which has lasted about nine months. Here, then, is jaundice depending upon obstruction preventing the flow of bile into the bowel; an obstruction of a chronic organic character. We have evidence of this in the enlargement of the gall bladder. In carcinoma of the liver we have a nodular condition appearing in the liver or in the gall bladder. It presses upon the biliary ducts, causing jaundice. If it press upon the larger ducts it will cause extreme jaundice. If upon the smaller ducts, the jaundice will not be so marked. In carcinoma of the liver the liver is enlarged, there are round projections

from it, and it is lobulated, not uniformly enlarged. All these things suggest carcinoma.

There is one important point against cancer, and that is the absence of pain. He has had no pain at all, not even when the mass has been handled and percussed. This is very unlike carcinoma. Again, while it is true that there is enlargement of the liver, the enlargement seems to be principally due to the dilated gall bladder, and to the tumor in the lelt lobe. On the right side we have the normal shape of the liver.

What other conditions could comply with the symptoms? We find the liver enlarged where there is chronic congestion with fatty degeneration. There is a form of cirrhosis of the liver with enlargement; but in cirrhosis with enlargement, although there often is jaundice, there is no cause to explain the enlargement at the left lobe nor this great dilatation of the gall bladder.

Another cause of enlargement is albuminoid degeneration. It is apt to arise in phthisis and constitutional syphilis. Our patient had, long ago, syphilis. In albuminoid degeneration, the liver usually retains its shape, but rarely is there any jaundice. Frequently in albuminoid degeneration of the liver, the kidneys and spleen are involved. They are not enlarged in this case. In albuminoid enlargement then, we have the liver simply enlarged, without pressure on the bile ducts and without jaundice. Frequently the disease will run its entire course without a trace of jaundice.

Let us examine the other lesions and see to what diagnosis they point. We have here aortic disease and widespread atheroma of the arteries. With syphilis we would be apt to have these lesions occurring. Heart disease with carcinoma is rare; but here we have heart disease and widespread atheroma, as we often find in the later stages of syphilis.

Suppose, now, that this is a case of albuminoid enlargement of the liver, with the same change in the glands in the fissure of the liver, forming the mass which I feel, and pressing upon the duct of the gall bladder; that would be a sufficient explanation of the symptoms we have here. We would be more apt to have œdema in that condition. We would be more apt to have nutrition well retained, and absence of pain, as we have here.

This is either carcinoma or syphilitic disease of the liver. I cannot now say which it is. It would be odd to have carcinoma with such good health; and, on the other hand, it would be odd to have such immense albuminoid enlargement without lesion of other organs. I tend to the opinion that it is syphilitic disease.

If it were carcinoma, there would be absolutely no indications for treatment, for the man has no pain and his nutrition is good. If it is syphilitic, we have more hope of doing good. If this be the result of a long standing constitutional taint, there is more hope of promoting the absorption of this man. I have been treating on this view. I first gave him a pill containing —

℞.	Hydrarg. iodidi viridis,	gr. $\frac{1}{6}$	
	Ext. nucis vomicæ,	gr. $\frac{1}{4}$	
	Ext. gentianæ,	gr. j.	M.

But later, finding that the œdema was becoming more marked, and that the jaundice still continued, I substituted a solution of iodide of potassium and bichloride of mercury. We are also giving digitalis. We will watch this case with great interest. If the disease be syphilitic, we shall expect some benefit from our treatment. We leave the diabetes out of the case altogether, as the amount of sugar and the quantity of urine passed are not very great. I will bring these patients before you again, in order that you may see the result.

Autopsy.

October 11th. Gentlemen: You will remember that when I showed you the patient with aortic disease, atheroma of the arteries, distended gall bladder and a tumor in the epigastrium, I also pointed out to you the dropsical condition of his legs. This continued, and his urine lessened in quantity, until he passed only four or five ounces during the twenty-four hours. It became intensely marked with bile; until the last, it contained sugar, but no albumen; the quantity became so reduced that it amounted to complete suppression. The dropsy and ascites increased, and he sank into a state of painless coma, and passed away quietly. This case has been before you so often that I shall not go over the symptoms.

There was one point of grave interest connected with this case, and that was, whether this was a malignant, cancerous affection, or one due to syphilis. I told you, in the lengthy remarks which I made on this subject, that the case presented peculiarities that made either of these views difficult to adopt.

Examining the specimens before me, I find the pulmonary artery healthy; but there is intense disease of the aorta—hard, bony masses project from its surface. The aortic valve is thickened, rigid and useless. The mitral valve does not appear to be affected, and there was no murmur connected with this valve. There was a loud systolic murmur caused by the resistance to the passage of blood through the aortic valve. This atheroma is not limited to the arch, but extends to the whole aorta. The abdominal aorta feels like a tube of stone. There is entire calcification of the arterial system; it extends out through the divisions of the aorta. Now this arterial lesion was, as I stated to you, rather in favor of the affection being syphilitic. We do meet with cancer in heart affections, but it is very rare.

We found the liver enlarged, extending two inches below the ribs. Projecting two inches below this there was a hard, round tumor, and as I felt it it seemed to convey to my hand a sense of fluctuation. From its ovoid shape, indistinct fluctuation, position and continuity with the liver, I diagnosed it to be the distended gall bladder. You see that this view was correct. It probably measures seven inches in length and three or four inches in breadth, and contained more than half a pint of bile. We shall have to study carefully the cause to which this is due. You will remember that I attributed it to the pressure upon the cystic duct by the mass occupying the fissure of the liver. On pressing down deep into the epigastrium, I came across a mass, irregular and nodular, which occupied either the glands in the

fissure of the liver or some of the contiguous tissues.

Here is the stomach, which I shall remove. There was no evidence of implication of the stomach, there was no vomiting, and he enjoyed a remarkably good appetite until toward the close of life. I find that the stomach is easily separated from this mass, showing that it is not implicated. I will open it, and we find it filled with a horridly grumous fluid, but the mucous membrane is normal, and there is no organic lesion.

Placing these parts in their normal position, I find the left kidney, which is free, and I remove it. There was no albumen found in the urine. The kidneys are deeply stained with bile, as are all the tissues. They are enlarged, and I think the microscope will reveal some lesion of their structure.

We now see a mass lying in the region of the fissure of the liver, but it does not arise from the glands. What organ could give rise to this tumor? It might be the stomach, but that has been excluded. It was too deeply situated to be in the omentum. It might arise from the glands in the fissure of the liver, from the glands against the spine, or from the pancreas. It is connected with the pancreas. What I said to you the other day in regard to the implication of the pancreas in diabetes, makes this case very interesting. This mass evidently contains liquid. On cutting into this, I find plates and tubes of calcareous matter. The branches of the mesenteric arteries constitute regular tubes of calcareous matter. I feel these plates in every direction. We also find the pancreas filled with calculi. This is rather remarkable, coming in connection with those renal calculi in a previous case. This is a very rare condition. There are, perhaps, twenty calculi exposed by this section. I now open a cavity from which comes a considerable quantity of fluid. Within this cyst I find a number of smaller ones. This liquid must be carefully analyzed. While a syringe, with which to evacuate this, is being procured, I shall call attention to the capsule of the spleen. This organ is not much enlarged, but it is covered by a layer which feels like sole leather, and when it is cut through I find that it is a very extensive thickening of the capsule of the spleen, due to a chronic local peritonitis. This condition is very frequently found in old syphilitic subjects. Taking this in connection with the extensive changes in the vessels, I should be inclined to regard these lesions as syphilitic in their nature.

I have now evacuated this cyst and preserved its contents. I now come to a larger one, which contains the same kind of fluid. There is still a larger one to open, but this will be sufficient to show the nature of the change. I shall open the other one afterwards.

We have here, then, pancreatic calculi, with, evidently, chronic degeneration of the pancreas, tumor formed in its substance, and obstruction to its duct, whether by calculi or inflammation remains to be seen. We also have this mass pressing upon the cystic duct, causing enormous distention of the gall bladder; pressing, also, upon the vessels of the liver, causing enlargement of this organ; with this there is calcification of the aortic valves and of the aorta, not limited to the arch, but extending through the whole aorta and out into the small vessels; there is also this old local peritonitis. Therefore, taking all these changes together, I should, as I said before, be inclined to refer them to syphilitic disease. There has evidently been a great tendency to calcareous deposits, as is shown by these pancreatic calculi; we may also find them in the liver. This condition of the pancreas is very rare. I will have these fluids analyzed and the parts carefully dissected.

As far as the examination goes, it confirms the view that I expressed to you, except that I had no idea as to the nature of the tumor. I thought that it was due to enlargement of the glands at the fissure of the liver or of the head of the pancreas. It was situated so deeply, that I could not palpate it with sufficient care to detect fluctuation. A cyst of that size in the pancreas is so rare, that it would not have occurred to me to refer it to that cause.

Disease of the pancreas is exceedingly difficult to recognize with certainty. The reasons for this are obvious. In the first place, disease of this organ is rare, and in the second place, the organ is so deeply situated that we cannot easily reach it by palpation, and in so many cases there is tenderness over it, that prevents palpation, and again, in so many cases, it is connected with disease of the stomach or liver, which also prevents us from reaching it. Lastly, we know so little of the function of the pancreas in health, that it makes it very difficult to recognize any disorder of its function.

Take this last question, as to the function of the pancreas. The pancreas is concerned in the intestinal digestion of fats and the conversion of amylaceous matter into sugar, so that in a case of pancreatic disease we should look for fat in the stools and sugar in the urine. In this case there was no excess of fat in the fæces, at least, so far as could be determined by inspection. The stools were not subjected to distillation with ether. We did find sugar in the urine in this case, and when I pointed out to you the remarkable complication in this case, I called your attention to the fact that in some cases of diabetes the pancreas had been found diseased; but in this case the liver was so much diseased, and, as we often find diabetes, connected with derangements of the liver, I naturally attributed the diabetes to the hepatic trouble.

Examining the specimens, we find that the liver is greatly enlarged and the gall bladder distended. We find that the tumor in the notch of the liver is formed by the pancreas. As we pass from the gall bladder to the cystic duct we find that they are separated by a septum. The common duct is patulous. The pancreatic duct cannot be found; there is no trace of it in the intestine. The tissue of the pancreas is in a state of cirrhosis, the gland structure being to a great extent removed, and the organ has undergone cystic degeneration, the intestinal tissue being thickened and fibrous. The walls of the pancreas are studded with calculi. As I advance to the head I find a cyst with a large number of calculi—I could pick them out by the dozen. Many of them are branched and resemble coral. So that here we find a degeneration of the substance of the

pancreas and the presence of a series of smooth, walled sacs, containing a large number of calculi. The largest cyst of all is separated by this central partition. It held several ounces of fluid, and from it was taken this very large calculus which I show you. This is one of the largest calculi in existence. It was the pressure of this cyst upon the hepatic ducts that gave rise to the jaundice, and it was probably the irritation caused by its pressure that gave rise to the obstruction of the cystic duct. The great distention of the gall bladder was not due to bile, but to the retention of the secretion from its own lining membrane. So then we have here one of the rarest forms of disease: impacted pancreatic calculi, complete obstruction of the duct of the pancreas followed by cystic degeneration, with fibrous thickening of its walls, complete obliteration of the cystic duct, immense distention of the gall bladder, and enlargement of the liver.

This patient also had double aortic disease, an intense grade of calcareous degeneration of the arteries throughout the body, jaundice and diabetes. I would remind you that we here had an anomalous state of things, for in urine with a specific gravity of only 1.009 we found a large proportion of sugar. We see now that in all probability the diabetes was dependent upon the disease of the pancreas, although it may have in part been due to the diseased liver.

When you have a case of suspected pancreatic disease, you will expect to find the following symptoms: Persistent, marked, progressive emaciation—our patient did not have marked emaciation; pain in the epigastrium and pain referred to a corresponding point in the back, because the pancreas presses upon the nerves as they issue from the spinal column—this man complained of no pain whatever; vomiting, because the pyloric extremity of the stomach is pressed upon—this man did not vomit, but ate heartily; jaundice from pressure upon the hepatic duct—this man had jaundice, and on pressure a mass might be detected deep in the epigastrium. In such a case we would study the urine for sugar and the stools for fat. Disease of the pancreas is usually cancerous or cystic. In this case, so few were the symptoms pointing to the pancreas, and so marked were the symptoms pointing to hepatic disease, that I should make the same diagnosis that I made in this case if I again had a case presenting the same symptoms. The diabetes was the only symptom pointing to pancreatic disease.

Periscope.

Nervous Exhaustion from Weak Vaso-motor System.

Dr. F. P. Atkinson writes, in the *Practitioner*, February, 1881: Some persons are the subjects of a naturally weak vaso-motor system, and Dr. Hume, in the *Practitioner* of July, 1879, has very accurately described the distinguishing characteristics of those who are so afflicted. "They have," he says, "a soft, moist eye, a dilated pupil in a blue iris, and a thick, drooping upper eyelid. The nervous system, not well balanced, is easily disturbed by excitement. The blood vascular system is weak, atonic, as shown by the irregular heart, subject to palpitations and tumultuous action on slight exertion or sudden emotions, the small irregular pulse, the tendency to dilatations, and eventually varicosities of the veins, and the ready congestion of the capillaries on exercise or alcohol being taken." From my own personal observation, I should say that those who are thus constituted require longer rest than other people, and are easily upset by the use of alcohol, smoking, residence in a damp-warm climate, and sexual intercourse. Sexual intercourse especially seems to produce such an excessive amount of nervous exhaustion that it is necessary we should be able to recognize at once both the symptoms and the cause, and also to apply the appropriate treatment. The chief symptom complained of is a sinking, or vacancy at the pit of the stomach, which nothing seems to relieve, not even food; with this there is a feeling of drowsiness, some pain and swimmy feeling in the head, and great irritability of temper. The patient's sleep is heavy, as shown by loud snoring, but it is unrefreshing, and broken by frequent and severe startings, or muscular twitchings. On rising in the morning the patient complains of feeling giddy and light-headed; the tongue is dry and coated, and there is a nasty taste in the mouth; the breath is exceedingly offensive (the result of nervous exhaustion); the forehead and the body generally is hot and dry; the eyes look congested. In bad cases the patient will tell you he does not seem to be able to pronounce his words correctly when reading aloud, or direct the movements of his hands as he wishes while writing, or his legs on walking. In very severe cases I have known complete loss of speech, varying from an hour, or so, to two or three days, and also of control over the movements, both of the legs and arms.

The treatment in these cases should, of course, be directed towards controlling the cerebral circulation, and with this view four minims of the dilute hydrocyanic acid should be given every four hours (this has a sedative effect on the brain, spinal cord, and heart). Bathing the head with *cold* water, two or three times in the day, should also be strongly recommended, inasmuch as it acts as a direct sedative to the cerebral circulation. More than one patient has told me that chocolate relieves the sinking feeling at the pit of the stomach, and produces a more lasting effect than anything else; but what is really its action I cannot say. Plenty of milk should be taken, but no alcohol. In severe and prolonged cases, when the immediate symptoms have passed off, syrup of the lactophosphate of lime and iron, with small doses of tincture of digitalis and nux

vomica, or Kirby's compound phosphorus pills, are to be recommended, together with change to a bracing atmosphere.

On Quebrachine.

In the *Berliner Klinische Wochenschrift*, No. 40 (1880), quoted in the *Chemist and Druggist*, it was pointed out that the bark of aspidosperma quebracho acts in many cases as an anti asthmatic, but the author of this paper, O. Hesse, not being able to attribute this action to the alkaloid found by Fraud in the bark, and called by him "aspidospermine," set to work to examine the bark more closely, and has found in it, besides 0.17 per cent. aspidospermine, as much as 0.28 per cent. of a new alkaloid, which he terms quebrachine.

Quebrachine is but slightly soluble in cold alcohol, but hot alcohol dissolves it more readily, and it crystallizes from a solution in small white anhydrous prisms. It is indifferently soluble in ether. Quebrachine melts at 214° to 216° C. under partial decomposition. Its chemical composition may be represented by the formula $C_{21}H_{22}N_2O_3$.

Quebrachine dissolves in pure concentrated sulphuric acid with a bluish tinge, which becomes darker upon standing. When lead peroxide of molybdic acid is present the coloration is quite instantaneous and very intense. A crystal of potassium bichromate dropped into a solution of quebrachine in sulphuric acid produces the same effect.

Boiled with a solution of perchloric acid quebrachine yields, like strychnine and curarine, a yellow decoction, but, although very poisonous, 0.04 g. being sufficient to kill a small rabbit, Penzoldt finds that its physiological action is not identical with strychnine.

Quebrachine is a strong vegetable base. Its alcoholic solution turns red litmus paper blue, and it completely neutralizes even strong acids.

The author has formed several salts of the base, some of which differ from the corresponding salts of aspidospermine by being less easily soluble in water.

The author reserves further details of his investigations for a future paper.

The Treatment of Cancer of the Tongue.

In the December number of the *Bull. et Mem. de la Soc. de Chir.* (quoted in London *Medical Record*), is a report of a communication by M. Verneuil on the inutility and danger of any save operative treatment of epithelioma of the tongue. This disease, it is pointed out, has never been cured, either by internal treatment or by topical applications. M. Verneuil states that he seldom meets with a case of lingual cancer which has not previously been treated by iodide of potassium. Such treatment, it is argued, cannot be justified. It is a gross error to think that iodide of potassium has any efficacy in instances of true neoplasm, for, as is well known, this agent effects no amelioration in cancers of the lip, cervix uteri, and other organs. The diagnosis of epithelioma of the tongue, in the majority of cases, should not be difficult; and through the recent teaching of M. Fournier this affection may be readily distinguished from tertiary glossitis. There are, it is true, hybrid cases in which the cancer occurs in a subject of old syphilis, and in which the objective characters of the epithelioma are modified by the constitutional affection. This condition does not indicate any alteration of treatment, for the hybrid affection, in its course, termination and prognosis, resembles pure epithelioma, and should be dealt with in a like manner. M. Verneuil asserts that medicinal treatment of cancer of the tongue is not only fruitless, but also hurtful. Surgical removal of the disease is postponed, and so much precious time is lost. Iodide of potassium often excites troublesome and obstinate glossitis, and mercury stimulates the growth both of the primary epithelioma, and of any affected cervical glands. Chlorate of potash is as useless in cases of cancer of the tongue, as it would be if given for the relief of cancer of the cervix uteri. Epithelioma of the tongue, M. Verneuil holds, if taken in time, may be cured by operation. Mention is made of four cases of complete cure. In three of these cases the growth was small and superficial; in the fourth case a relapsing growth, together with a degenerated gland, was removed. When more than a third of the tongue has become involved, when the floor of the mouth is also affected, and when the disease has been progressing for longer than a year, the case is deplorably grave, and cannot then be treated by operation with any chance of success. Removal of lingual cancer, it is asserted, is not a serious operation when it can be performed by the mouth, and when the disease is recent and not extensive. Of two hundred such operations performed under these conditions by M. Verneuil, one only was fatal; and, in this instance, the death was due to pneumonia, and not directly to surgical action. Operation at an early stage of the disease is strongly recommended; and it is stated that between the early and favorable stage and the advanced and hopeless stage there is a long interval, at any period of which the surgeon may operate without risk, and with some prospect of permanent success.

Bleeding in Tetanus.

The following heroic treatment is given by a correspondent of the *Druggists' Circular*, February, 1881:—

Peter Forbes, a colored man employed by a farmer, cut one of his fingers very severely. Little notice was taken of the cut at first, but the man was struck with the fact that the long gash in his finger was scarcely bleeding. He said nothing about it until next morning, when he awoke and found the muscles of his mouth all contracted, and felt unable to open it sufficiently to speak. A physician was called in, who, upon arriving, examined him, and told him he could do nothing for him, as his case was a fatal one. Having left the house, he was shortly after sent for a second time, and went through the same course as before, saying he could do nothing for the patient, that there was no cure for his case that he knew of, and then retired. Peter, thinking that he was going to die, thought he would

resort to some means himself, hoping to effect a cure. He went to a closet and found an old shoemaker's awl and sharpened it, then he sat down and commenced to draw it across his *tongue*, cutting long gashes in it. As soon as he cut the first gash he felt greatly relieved; shortly afterwards breathing became more easy and the muscles somewhat relaxed. He, finding this to answer so well, repeated the operation several times and effected a *speedy cure*. To-day he is well and hearty and at his work. This was pronounced by several doctors as a case of lockjaw.

On Pleural Effusions.

At a late meeting of the Medical Society of London, Dr. Broadbent read a paper upon "Some Points in the Clinical History of Effusion into the Pleural Cavity." He first enumerated and explained the relative importance of the physical signs of pleural effusion, and pointed out that the curved line of dullness was due to the manner in which the lung shrinks around its root, and as the fluid rises the vocal resonance and vibration becomes exaggerated over that part of the chest-wall where the lung is still in contact. When the cavity is full of fluid the respiratory murmur may be conducted for a short distance across the back from the unaffected lung. Sometimes, however, the lung was prevented from collapsing by adhesions, by consolidation, or congestion; and he believed the persistence of bronchial breathing in such cases was due to imperfect collapse of lung, although the fluid was in large amount. The chief point he wished to urge was that while the ordinary signs of effusion into the pleural cavity—dullness, extinction of vocal fremitus, diminution of vocal resonance, and limitation of bronchial breathing to the region of the root of the lung—show that the lung retreats and shrinks before the fluid, loud tubular breath sounds at the base of the lung posteriorly and over the lateral and anterior aspect of the chest show that the lung has not entirely retreated, but that it retains a certain volume, and is more or less deeply immersed in the fluid. The patency of the bronchi and the partial condensation of the lung favor the transmission of sonorous vibrations. It is in these circumstances that œgophony is heard most distinctly and widely—from the thin layer of fluid intercepting some vibrations and transmitting others—conditions which ordinarily exist only in the earlier stages of effusion. In some of these cases there may occur some degree of vocal vibration at a period when the amount of fluid is sufficient to give dullness on percussion over the entire lung. Paracentesis would be of comparatively little value in such conditions, for the quantity of fluid is small, and the consolidation of the lung would persist after its removal; and most cases of this sort get well without resort to paracentesis. In one such case only thirty ounces of fluid could be withdrawn. The conditions are met with in the pleural effusion of renal disease, often accompanied by congestion and partial consolidation of the lung, preventing its collapse: also, in effusions which rapidly became purulent, as in empyema in children. Apart from these cases, the signs indicative of a large congested lung deeply immersed in the fluid are prognostic of rapid absorption, and Dr. Broadbent had seen this now in a sufficient number of instances to enable him to predict with considerable confidence the recovery of the patient without paracentesis and in a comparatively short time. One of the first steps towards recovery is a rather sudden disappearance of the tubular breathing and the substitution of the more ordinary signs of simple effusion; and it is probable that the congested lung has relieved itself by diffusion of serum into the pleural cavity, and that the amount of fluid there is actually increased. In conclusion, Dr. Broadbent stated the rules which guide him in recommending paracentesis. It should be resorted to at once when there is serious continued or paroxysmal dyspnœa; but in the absence of urgent symptoms a week or ten days may be given after one side of the chest is full, on the chance that absorption may set in, and a longer period still when the lung has not greatly shrunk. Old age, phthisis, or a phthisical tendency, are reasons for early tapping, as also is the existence of disease of the kidneys. The spot for puncture is the eighth space, in a line with the angle of the scapula, and he had come to prefer the common trocar and cannula, with antiseptic precautions, to the aspirator. The whole of the fluid should never be removed, or attempted to be. Where the effusion has lasted some time frequent partial emptyings are to be preferred.

Unilateral Hypertrophy of the Head.

A curious example of this was lately shown to the Pathological Society of London, by Mr. Barwell. He had first come across the boy, who was then seven years old, in the country, about six years ago. He had kept the case under observation, and some time afterward tied the carotid artery on the right, which was the affected side; the object of the operation being, not any great hope that it would alone lead to benefit, but to facilitate future operations. Six days afterward he died, of a not very copious secondary hemorrhage. The deformity had been present at birth, but had grown more marked with his growth. The right side of the face was twice as broad and one and a half times as long as the left. Near the ear was a patch of ichthyosis, which was increasing rapidly at the time of the operation. The enlargement was not due to cystic disease; for the enlarged parts were of a natural consistency; and the bones, as evidenced by a cast of the alveolar processes, had participated in the increase; and the sutures had been pushed over to the left. The right half of the tongue also was greatly enlarged. Mr. Barwell observed that the deformity might have been due to some functional derangement of the sympathetic, or, perhaps, as was suggested by the occurrence of secondary hemorrhage, to some imperfect development of the middle coat of the arteries. Unilateral overgrowth, to a slighter extent, was not very unusual, and Mr. Barwell had met with several cases. The slighter degrees of overgrowth of one side of the trunk were in some cases the often-overlooked cause of lateral curvature. It was nearly always the right side which was thus hypertrophied, the left being affected only once in fifteen cases.

Reviews and Book Notices.

BOOK NOTICES.

The Hygiene and Treatment of Catarrh. Part I. Hygienic and Sanative Measures. Part II. Therapeutic Measures. With 40 Illustrations. By Thos. F. Rumbold, M.D., St. Louis Geo. O. Rumbold & Co. 1881. Cloth, 8vo. pp. 473.

The wide prevalence of chronic catarrh, especially in the Mississippi Valley, has been prominently brought to the notice of the readers of this journal during the last few months. One writer has said that it may be called almost universally present in Iowa. It is remarkably obstinate, and is notoriously disagreeable to the patient, and his or her friends, and generally the despair and annoyance of the physician.

Dr. Rumbold, therefore, has done a real service to the profession by devoting to this complaint the full monograph before us. It is not a compilation, but the result of twenty years' study of the disease, and the careful analysis of very many cases. He does not promise any magic remedy, but describes in detail the particular sanitary measures, the operative procedures, and the local and general medication which must be persistently, patiently, and discriminately applied, in order to conquer the various forms of this rebellious malady. He uses a large variety of instruments, nearly all of which he has devised himself, and which he figures and describes. His objections to the use of the Eustachian catheter merit special consideration.

There are many original suggestions and observations on the anatomy and functions of the naso pharyngeal organs, and on the methods of their therapeusis, scattered through his pages, which cannot fail to attract attention. We can speak of it as the most exhaustive essay on the subject in any tongue, and one highly creditable to American medical literature.

Manual of the Physical Diagnosis of Diseases of the Heart, including the use of the Sphygmograph and Cardiograph. By Arthur Ernest Sansom, M.D. Third Edition. Philadelphia, P. Blakiston, 1881. Cloth, 12mo, pp. 300. Price $2.00.

Aids to Diagnosis. Part I. Semeiology. By J. Milner Fothergill, M.D. Part II. Physical. By John C. Thorowgood, M.D. pp. 61, 75. 16mo. Each, cloth, 50 cents. G. P. Putnam's Sons, New York City.

The third edition of Dr. Sansom's work is quite three times as large as the first, and the additions have been made with good judgment. Most of the increase is taken up with the descriptions of the sphygmograph and cardiograph, instruments which the author thinks should now be in frequent use by every educated physician. The value of their evidence, he maintains, is now attested by daily experience. The directions for their use are clear and full, and any one who wishes to familiarize himself with them will find no better guide. We do not observe much change in the other portions of the work, except some more detail on the cardiac action.

The two small works whose titles are given belong to the "Student's Aid Series," published in London. They are what may be called primers of medicine, and are largely used by the London students for "cramming" for an examination. Probably they are well suited for that purpose, but an examination of them leads us to doubt the utility of introducing them to American students; there are other works, better for this purpose, from American writers, and the second one named strikes us as quite superficial.

A Text-book of Human Physiology. By Austin Flint, Jr., M.D., etc. Third Edition, Revised and Corrected. New York, D. Appleton & Co., 1881. 1 vol., cloth, pp. 977. Price $6.

The author of this work takes rank among the very foremost physiologists of the day, and the care which he has bestowed in bringing this third edition of his text-book up to the present position of his science is exhibited in every chapter. A good portion of it has been rewritten, and such new views as the probable generation of heat in the body by the union of oxygen and hydrogen, and the formation of water; the discovery of the retinal red; the recent theories of the functions of the Malpighian bodies; the mechanism of micturition, as now understood, etc., have received such explanation as will render them familiar to students and readers.

The pages are freely illustrated, there being in all three hundred and fifteen wood-cuts and three lithographic plates, the latter showing embryological development.

The criticism that may fairly be made on the volume is that it is too large for a text-book. There are nearly one thousand pages, in such small type that each page has on an average eight hundred words! It appears to us this is entirely too massive a treatise to put into the hands of medical students. The author has not or does not care to exercise the faculty of judicious condensation. It could profitably be called upon in many portions of his work.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

INFANT MORTALITY, ITS CAUSES AND PREVENTION.

If the preservation of life is the main object of medicine, as many assert, there then is no department of it that demands more vigilant attention than the condition of the individual during the period of infancy and childhood, for it is then that by far the heaviest mortality occurs; it is then that existence runs its greatest risks.

This is strongly illustrated by the examination of vital statistics. Thus, in England, according to MR. BROWNING, among the poorer population of the large cities the child death-rate usually amounts to half (fifty per cent.) of the total deaths at all ages, and occasionally exceeds sixty per cent. of those total deaths, while in all England the child death-rate is only twenty-five per cent. of the total deaths, and is, as a rule, less than this in the healthy districts and among families comfortably off. In proportion to the higher social position of the parents, the child death-rate is everywhere diminished, so that among one hundred children of the upper and middle classes it does not average more than four casualties yearly, while it ranges from ten to twenty-six, seventy, and even ninety, in some of the poor quarters of the cities. Of 1,000,000 children of all ranks born in England, some 260,000 do not reach their fifth year. In the unhealthy districts at least 500,000, and in some places 920,000, working-class children, out of each 1,000,000 born, fail to reach the age of five years. These last figures are simply appalling.

Yet even these figures are rather more favorable than others in the Old World. Take Spain, for example: As in most of the southern countries of Europe, the rate of infant mortality in Spain is terribly high. During last November, the mortality of infants under one year of age was equal to two hundred and forty-two per thousand of the recorded births, not far short of twice the rate prevailing in England and Wales.

We have at sundry times given statistics of the mortality of infancy and childhood in the United States, which show that we have little to boast of in comparison. With us, as in the Old World,

no decade of life approaches in peril the first one.

When we come to analyze the causes of this excess of deaths over other periods of life, there are several which at once suggest themselves. Many cases of so-called still-born children, and many which die within a day or so of birth, are attributable to the ignorance or carelessness of midwives, who do not use the proper means to resuscitate the asphyxiated neonatus, or neglect it, either through carelessness or design. The parents often have more children already than is agreeable to them, and they are not urgent that every possible means be resorted to to preserve the unwelcome addition to their crowded board.

Improper food is another widely destructive agent; perhaps none more so. Disorders of nutrition and intestinal diseases carry off tens of thousands in the first and second years of life. When a child has to be reared "on the bottle," or one of the numberless "infant foods" which are in the market, its chance for life is at once materially diminished. Add to this the ignorance of most mothers on the whole subject of the proper feeding of babies, and the risk, even under favorable circumstances, is great indeed.

Hereditary diseases form another special danger at this epoch. Some of them expend their principal force on the extremely young. Take one which is very widely disseminated, more so than even most physicians choose to believe, syphilis; its transmitted forms explode with most destructiveness upon the tender infant, predisposing it to succumb to slight maladies, and poisoning its nervous and nutritive activities, so that the child dies through those mysterious and vague maladies called marasmus, fits, congestion of the brain, etc., which figure so largely in the older mortality reports. Scrofula, too, impresses its deteriorating power chiefly on the tissues of the very young, leading to degeneration of tissue and disturbance of physiological function.

Childhood, again, is the season of epidemic diseases. There is a formidable group of these which are distinguished as "diseases of children;" not that they are confined to childhood, but that they are so much more prevalent and dangerous in patients at that age. In accordance with one theory, of doubtful authenticity, they belong to the class of "zymotic" diseases, their exciting cause being, perhaps, the presence and development in the economy of certain low organic forms. Their greater virulence in children may be explained either by the supposition that their active poisons find a more congenial soil for growth in the tender tissues and rapid vital changes of the young; or that the law of "the extinction of the unfit" (which is the correct expression for the survival of the fittest) is in more active operation in early life—as it naturally would be.

These four causes: neglect at birth, improper feeding, hereditary disease, and epidemics, explain a great deal of the excess of the mortality of infant over adult life. There are also to be taken into account the greater liability of children to accidents; their diminished resistance to extremes of temperature, heightened by improper clothing; their ignorance about the commonest sanitary precautions; and their want of self-control over their appetites and passions.

The practical question arises, how far are the causes above enumerated capable of being modified or removed. That with proper surroundings they can be greatly reduced is evident from the English statistics above quoted, where the annual mortality is reduced from ninety per cent. in one class of society down to four per cent. in another! A truly wonderful contrast!

As, however, it is simply impossible to make all classes rich, sober, wise and dwellers in healthy country districts, the next best resource is, in the opinion of many, to establish large sanitaria for children, where they can be received and cared for under the best surroundings.

Beginning with early life, the first of these institutions must be foundling hospitals. Foundlings in America are generally sent to the almshouse, no special provision being made for their reception or care. They are generally picked up in the street by a policeman, after they have been exposed to cold and want. Their consequent death-rate is needlessly high. In Paris there is

now an institution known as that of the "Enfants Assistés." This institution replaces to a certain extent the old "Tour des Enfants Trouvés," where the children of indigents, or those abandoned by their parents, are, up to the age of sixteen or eighteen, admitted and maintained at the expense of the municipality. The number of children thus taken care of amounts, in the department of the Seine alone, to 27,000, involving an expenditure of 4,000,000 francs, or $800,000. During the last year no fewer than 3200 newborn infants, abandoned by their parents, were admitted into this institution.

We believe that such institutions are considered immoral by a certain number of virtuous women and unco guid men in the United States, so, perhaps, we had better not advocate this humane care for these wretched infants, but leave them to be thrown down cesspools and left to die in side streets. Public morality, it is said, is greatly enhanced by thus disposing of the fruit of illicit love.

Less objections can be urged to orphan asylums, and their benefit is undeniable. Mr. Browning, whom we have already quoted, and who is an English Health Officer of merit, makes the really extraordinary statement that, in nine large orphan asylums near London, whose inmates are, as a class, naturally of the feeblest constitutional type, mostly inheriting scrofulous, syphilitic, and alcoholismic diatheses, the average annual mortality is but 3 per 1000, or 0.3 per cent.

Such results have stimulated philanthropists to increase such institutions. We observe it lately noted that the Russian Society of Public Health is actively engaged in endeavoring to promote the foundation of sanitary colonies for the treatment of children suffering from chronic diseases.

The establishment of summer sanitaria, and of children's colonies, during the hot months, has been a genuine blessing to the poor infants of our crowded eastern cities. Their few days among the flowers, in the woods and through the valleys of the country, in June and July, are like a glimpse of heaven to these dwellers of reeking slums and foul alleys. As the season is approaching when this estimable charity will again begin its labors, let each speak for it, and work for it, as opportunity offers.

Notes and Comments.

An Instance of Movable Liver.

In the *Wiener Med. Blätt*, is recorded an observation accidentally made on a physician by Dr. Chvostek. There were no symptoms whatever of anything wrong in the abdomen, and there was no history of violence, or of any occurrence that threw light upon the condition. When the man stood up, the upper and posterior border of the liver was felt to come forward from under the margin of the thorax, and to be six centimeters and a half below the tip of the xiphoid cartilage in the right parasternal line, and one centimeter below that point in the left parasternal line. The left end of the liver was plainly felt through the abdominal wall, and from it the anterior, or rather the lower edge of the liver could be traced arching down to the right, being in the middle line fifteen centimeters below the xiphoid process, and in the right nipple and axillary lines respectively seven and one-and-a-half to two cent meters below the edge of the thorax. The liver did not markedly descend on taking a deep inspiration. In the horizontal posture it could be replaced under the ribs to a considerable extent. In lying on one side the organ fell to some extent toward the dependent side. The lower edge of the suspensory ligament could be felt tightly stretched, but this produced no pain, and so completely absent were all symptoms that the condition was only discovered accidentally.

Intravenous Injection of Ammonia.

Mr. Thomas E. Clark, of Bristol, states (*Brit. Med. Journ.*, March 12th), that he has tried this in surgical collapse, with promising results, and adds:—

"I feel sure that in many cases of supposed collapse from hemorrhage the collapse is due, not so much to the loss of blood, as to nervous shock; and, therefore, ammonia is more likely to be beneficial than transfusion of blood. There are many cases of collapse from nervous shock in midwifery practice which would be benefited, if not saved, were the cause more thoroughly understood; there is not time for remedies to reach the system other than by being placed directly in the venous channels."

On Congestive Dysmenorrhœa.

At the conclusion of an article in the *Lancet*, Mr. Herman states his conclusions on this subject as follows:—

1. The term *congestive dysmenorrhœa* is one which has no definite and generally accepted meaning. but is applied by different authors to different conditions.

2. That there is a form of dysmenorrhœa characterized by deficiency in the quantity of the flow, with increase in the pain, these changes occurring in a patient whose general condition is not such as would cause menstruation to become scanty, and who is otherwise in good health.

3. In such cases local depletion always relieves, and if the changes be recent, cures, the patient.

4 That in these cases the absence of appreciable morbid conditions other than congestion, and the prompt relief by local depletion, give good reason for thinking that the pain is due to congestion.

5. That it would be well either to restrict the term "congestive dysmenorrhœa" to these cases alone, or at least to separate such cases from all the other forms of disease to which the term congestive dysmenorrhœa has been applied, the adjective *primary* being suggested as the best distinguishing prefix.

The Causation of the Uniformly Small Pelvis.

Dr. P. Müller writes upon the frequency and etiology of the uniformly narrow pelvis (*Archiv für Gynäkologie*). He thinks that narrow pelves are more common than is supposed; that they are thought rare because obstetricians do not systematically measure the pelvis. Out of 1177 cases in his clinique in which the pelvis was measured, he found the following number of cases of the different pelvic deformities: 1. The flat pelvis, 95 (simply flat, 86, rachitic, 9). 2. Generally contracted pelvis, 88 (generally contracted simply, 71, generally contracted and flat, 4, generally contracted and rachitic, 12. 3. Osteomalacic, 2. 4. Obliquely contracted pelvis, 2. 5. Funnel-shaped pelvis, 4. The following are the conclusions as to its etiology to which he has arrived: (1.) He believes he has brought forward proof that in his part of the world (Berne) the generally contracted pelvis, which elsewhere is seldom met with, occurs with exceptional frequency. (2.) That rickets contributes much more to its production than is generally admitted. (3.) He is inclined to assert that among the large number of pelves belonging to this category which are not rachitic, cretinism is a causal condition in not a few, and that it is highly probable that in the Berne district this condition plays a part in the etiology of this kind of pelvic deformity. His last conclusion is a practical one. (4.) That in a large majority of these cases the development of the fœtus is such that its small size diminishes considerably the risks of labor.

The Treatment of Burns.

The London *Medical Record* gives the treatment pursued by a writer, who, as physician in chief to a large iron mining and smelting company in Styria, has cases of burns very frequently presented for treatment, and has found the following method most successful. The wound is first cleaned (without opening the blisters), then disinfected with a two per cent. solution of carbolic acid, and covered with a thick furniture varnish, prepared from linseed oil and litharge, in which five per cent. of salicylic acid has been dissolved by warming. The varnish is allowed to dry and another coat applied; over this a layer of Bruns' cotton is placed, about two thirds centimeter in thickness. The wound seldom suppurates, generally healing under the varnish, which is finally removed as a dry pellicle, no change of the dressing having been necessary. Should, however, suppuration be indicated by the setting in of fever, or by the occurrence of painfulness, the dressing is removed from this locality; if the spot be not over five centimeters in diameter, nothing further is done than to strew the moist surface with dry powdered salicylic acid; if larger, an opening is cut in the dressing, the salicylic acid is applied as before, and then covered with a fresh layer of cotton. The scars become, by this method, entirely smooth, white, and are not hypertrophied.

Rational Sundays.

The *Lancet* and other leading medical and lay journals have expressed themselves decidedly in favor of having the British Museum open on Sundays. A petition "in favor of a rational Sabbath," from the medical students of London, has been proposed. The opposition to such measures is gradually weakening in both England and this country, and the intelligent public are yearly becoming convinced that it is better for the health and morals of that large class who have to work six days out of seven, that some better entertainment should be provided for them on Sunday than walking the streets or befogging themselves in drinking saloons.

Special Reports.

NO. IX.—OPHTHALMOLOGY.

BY C. S. TURNBULL, M.D.

As the annual literature of ophthalmology is more than any one man in active practice, even in that department alone, can manage to read, though he religiously devote every spare moment to his journals (special or general), it has been our aim, according to a wish expressed by the editor of the Medical and Surgical Reporter, to furnish ophthalmological notes of interest and practical value to the general practitioner.

In attempting to review this special department of medicine, we are, of necessity, deeply indebted to the *Archives of Ophthalmology*, edited by Dr. H. Knapp, of New York, in conjunction with other eminent ophthalmologists from all parts of the world.

We have endeavored, in every instance, to mention the source from whence information has been derived, and have presumed, when points of peculiar interest have arisen, by adding notes based upon personal experience and the early training under Dr. H. Knapp, who was the first to inspire us with an appreciative admiration for this branch of medicine.

Apart from what is contained in special journals it is almost impossible to pick up a modern medical periodical without being able, before closing the same, to learn some fact of ocular importance, and it is for those who are actively engaged in general practice, and who must read as they go, that we have endeavored to collect and condense items of practical interest in ophthalmology, and have not deemed it advisable to refer to other than recent articles. We have commenced with a reference to vol. xliv, No. 14, of this journal, which contains a review of the Transactions of the American Ophthalmological Society, Newport, 1880.

Under the title of Ophthalmic Miscellanies, (*A. f. O.*, Vol. ix, No. 3, p. 279), F. C. Hotz, M.D., of Chicago, reports a case of

Tonic Blepharospasm of Five Months' Duration Relieved by one Application of Tincture of Iodine.

Miss Martha I., aged 17 years, American, was admitted to the Illinois Charitable Eye and Ear Infirmary on the 9th of March, because for five months she had not been able to open her right eye. Nine years ago she received a severe blow upon the right eyebrow with a piece of wood, and four months later a piece of dry bread was thrown at her eye. These accidents, however, did not seem to be of any consequence, for the eye continued to be as good and strong as the other, until one year ago last fall, when both eyes became very red and painful. The inflammation (which probably was phlyctenular keratitis) was particularly in the right eye, and lasted three months. Then her eyes were well again until five months ago, when she had "erysipelas of the eyelids;" the lids of the right eye were swollen and red, and when the swelling had disappeared she could not raise the upper lid; and, in spite of various remedies her physicians had tried, the right eye remained closed.

The examination revealed a very remarkable tetanic contraction of the supra-orbital portion of the right orbicularis muscle. The eyebrow was drawn down, being considerably lower than that of the left eye; it covered the whole upper lid, so that the ciliæ only were visible. The integument of the region of the eyebrow was neither red nor swollen, nor tender on pressure, but it was firm, like a contracted muscle, and the patient felt an unpleasant soreness in it. Nowhere about the head or neck could I find any "pressure point;" but when the eyebrow was lifted up and held in its natural position by a gentle pressure of the finger against the supra-orbital margin, the patient could at once open her right eye without the least difficulty; the tarsal skin appeared perfectly smooth, there being evidently no spasm of the lid portion of the orbicularis muscle. As soon as the finger was withdrawn from the eyebrow, it was drawn down and the eye closed again. Electricity had no effect upon this spasm. The eye was very hypermetropic; showed considerable hyperæmia of the ocular conjunctiva and several superficial opacities in the cornea.

Thinking the blepharospasm might, perhaps, have been caused by spasm of accommodation, or by irritation of the corneal nerves, I instilled atropine. But the repeated use of the ($\frac{4}{5}$ per cent.) solution did not affect the spasm. Before and after atropinization V. $= \frac{20}{50}$; H. $= \frac{1}{12}$; L. E. V. $= \frac{20}{20}$; H. $= \frac{1}{12}$; cornea normal. At a loss what further to suggest, I remembered a case of persistent blepharospasm, which Prof. Zehender relieved by the use of tincture of iodine. And, *ut aliquid fiat*, I penciled tincture of iodine into the region of the right brow. The effect was like a miracle; after two minutes the muscle was relaxed, the eyebrow had recovered its natural position, and the patient could open and shut the eye at will. But, strange to say, on the following day the right lower lid, which had been perfectly normal, was inverted. It was a spastic entropion, which was easily relieved by a slight traction upon the lid. During the day the lid retained its normal position, but became inverted again during the night. On March 16th, therefore, I applied tincture of iodine upon the integument of the lower lid, with the same happy effect as in the case of the upper lid. The spasm was relieved and did not recur, although soon afterward (from March 18th to 24th) the patient had an attack of erysipelas of the right side of the face. On April 3d she left the infirmary.

Dr. H. Knapp mentions

Some New Ophthalmoscopic Changes from Concussion of the Retina.

K. was struck with the peculiar ophthalmo-

scopic appearance of an eye which the patient had hurt against a hard object.

"He came to the clinic day after day. His sight was somewhat dimmed, and in the outer part, where the eye had been hurt, the conjunctiva was slightly œdematous and suffused with blood. The refracting media were clear, the pupil was regular in shape and mobility, the lens was in position and uninjured; but at the periphery of the outer upper quadrant of the fundus the *retina was milky-white, interspersed with some punctate hemorrhages* in an area about four times the extent of the optic disc. The milky patch was whitest in the centre, and at the edges faded away gradually into the healthy background. There was no other abnormity in that eye. When I saw the patient again, in a few days after, the patch was much less opaque, having a whitish-red color; and after some days more, when I saw him again, it had disappeared, just as had the œdema and suffusion of the conjunctiva. His sight was normal. * * * * * * * For this peculiar white opacity of the retina, I know no other cause than concussion. It resembled the opacity we notice after embolism of the central retinal artery, but the picture was still more similar to that which we see after resection of the optic nerve, when, as is frequently the case, the blood vessels remain filled. It disappears in the same way, only more rapidly. I do not remember having seen it in other cases, though I have no doubt that it is of frequent occurrence, only overlooked on account of its evanescent character and the absence of marked and lasting functional disturbances. I wanted to put it on record as an objective symptom of concussion of the retina, which probably has been noticed also by other observers."—*A. f. O*, Vol. IX, No. 3.

Dr. Swan M. Burnett, of Washington, reports (*A. f. O.*, Vol. IX, No. 3), an abstract of ophthalmological papers read at the last meeting (31st) of the American Medical Association, among which was one by Dr. E. Gruening, of New York, who exhibited a

Magnet for the Removal of Particles of Steel and Iron from the Interior of the Eye.

Dr. G. has been experimenting for some time with various forms of magnetic apparatus, with the view to making an instrument possessing the greatest amount of magnetic polarity within the least possible dimensions. He first tries a well magnetized steel cylinder, filed to a long, slender point. This, however, was not satisfactory, since its polarity was feeble and the point was easily broken. He then fitted a needle of iron into the steel magnet, and found it to act stronger, and the needle did not become brittle. He then joined a number of cylinders together, and united them with a cap at each end; and at one end he inserted a needle 52 mm. long, 1 mm. wide, and 0.3 mm. thick. His present instrument will support a key weighing 28 grams. In order that the instrument may not lose any of its power, it is provided with a keeper which joins the two ends, and thus keeps the current of magnetism within the magazine.

The Detection of the Presence and Location of Pieces of Steel and Iron in the Eye by the Indications of a Magnetic Needle,

was the subject of a paper by Dr. T. R. Pooley, of New York.

The idea was first suggested to the author by some experiments of his brother, Prof. J. H. Pooley, of Columbus, on the detection of such bodies in other portions of the body. Dr. Pooley detailed at length the experiments he had made on the eyes of animals, and the conclusions he feels justified in arriving at are as follows:—

"That a steel or iron body may be detected by a suspended magnet when the body lies near its surface. The presence and position of such a foreign body may most surely be found by making it magnetic by induction, and then testing for it by a minute suspended magnet. The intensity of deflection of the needle is proportionate to the depth of the body. Changes of deflection of the needle indicate changes of position of the foreign body."

Where a foreign body, especially a piece of metal, has entered the *interior* of the eye, our advice, in the majority of cases, would be to enucleate the eye. If the body can be seen an attempt at removal would be justifiable. The incision must be made behind the ora serrata, and the foreign-body hook of Knapp be used under illumination. If attempts at removal should prove unsuccessful, enucleation can be resorted to.

From the "Quarterly Abstract of American Ophthalmic Literature," by Dr. S. M. Burnett (*A. f. O.*, Vol. IX, No. 3), we select the following:—

Traumatic Astigmatism.

Dr. J. B. Roberts, *Medical Gazette*, February 21st, refers to astigmatism after cataract operation, which he has found to vary from $\frac{1}{15}$ to $\frac{1}{30}$, and the astigmatism resulting from corneal ulcers. The last is mostly irregular, but still, benefit is often found from the employment of cylindrical glasses."

On the Relative Value of Atropia and Duboisia in Ophthalmic Practice.

By S. D. Risley. *American Journal of Medical Science*, April:—

R. has used duboisia in 140 cases for paralyzing accommodation in testing refraction. From a study of its use in these cases and in inflammatory affections, he arrives at the following conclusions:—

1. That in solutions not stronger than two grains to the ounce, duboisia sulphate is free from danger. 2. That the duboisia sulphate more rapidly paralyzes the ciliary muscle than a four-grain solution of atropia sulphate. 3. That the duration of its effect is less than half that of atropia sulphate. 4. That the preparations now in the market are more liable to irritate the conjunctiva than neutral solutions of the sulphate of atropia. 5. That in the treatment of inflammations of the eye, duboisia is quite as useful as atropia, and may, therefore, be used as a substitute.

The same author contributes an interesting paper on "Homatropin Hydrobromate as a Mydriatic." *American Journal Medical Science*, January, 1881

A New Operation for Symblepharon, and Permanent Cure.

By E. McFarlan. New York *Medical Record*, April 10th:—

The attachment was below. The lid was dissected upon a pin passed horizontally through the integument; another pin was passed through the cheek, parallel to this one, and the two were united by a figure of-eight ligature, thus producing a temporary ectropion. As soon as the conjunctiva had healed, the ligature and pins were removed and the difficulty was found to be permanently relieved.

The Parasitic Theory in Ophthalmology.

By W. W. Seely. Cincinnati *Lancet and Clinic*, April 17th:—

Dr. S. puts himself on record in regard to this theory as follows: "The danger in all conjunctival inflammations is corneal complication; and that that complication comes from infection, I believe, will hardly be denied; and, furthermore, that the infection arises from losses of corneal epithelium allowing entrance to the germs; and, furthermore still, that in a vast number of cases the erosions are brought about by the officiousness of the surgeon and his injurious remedies, I firmly believe."

Concerning lesions of the cornea I fully concur with Dr. S. Sins against poor inflamed eyes are oftenest those of commission; would they were of omission; nature would have a better chance.

The Value of Salicylic Acid in Treatment of Rheumatic Diseases of the Eye.

By F. C. Hotz. Chicago *Med. and Surg. Exam.*, May:—

Four cases of acute iritis, of probable rheumatic origin, are given, in which salicylicate of soda was administered, in addition to the usual treatment, with good results; and two cases of paralysis of the motor oculi nerve were much benefited by salicylic acid, and in doses of 0.15 to 0.25 every three or four hours.

We have had equally good results in the use of salicylate of quinia in cases of rheumatic iritis.

On Gonorrhœic Irido-choroiditis.

By C. J. Kipp. New York *Med. Record*, June 26th:—

K. gives the detailed history of three cases in which there seemed to be no doubt of the connection between the uveal inflammation and urethral discharge.

A Case of Mixed Astigmatism, Supposed to have been Caused by the Sucking of the Eye by an Infant.

By D. Webster. New York *Medical Record*, July 10th:—

One eye was emmetropic, the other had V. = $\frac{8}{100}$, but it was raised to $\frac{20}{20}$ by $-\frac{1}{10}$ c, axis 70°, combined with $+\frac{1}{4\frac{1}{2}}$ c, axis 160°. Vision in the lost eye was said to have been normal until after a period, when, to quiet her infant, she allowed it to suck her eye.

The Anæsthetic Effect of Cold upon the Cornea as a Therapeutic Measure.

By H. S. Oppenheimer. New York *Med. Jour.*, July:—

For the relief of all those symptoms due to hyperæsthesia of the cornea, photophobia, pain, blepharospasm, etc., Oppenheimer was induced to try melted ice dropped into the eye. He has found it useful in all forms of corneal inflammation, except, perhaps, the suppurative. He directs the water to be dropped in the eye every few minutes, from half an hour to an hour, lengthening the interval as the symptoms improve. He has used it in twenty five cases.

We have for the same symptoms used muriate of morphia (pure) with marked beneficial effects, especially when combined with equal parts of atropine or eserine in solutions.

On the Nature of Cataract and its Treatment by Electricity, with the Report of a Case.

By E. Evetzky. New York *Med. Jour.*, July:—

Dr. Neftel is the originator of a recent discussion of the influence of electricity in the progress of cataract, by his article in *Virchow's Archives*, Bd. 79, p 465. The extravagant claims there set forth, and further promulgated in this country through the columns of the *Churchman* newspaper, have been successfully met by Drs. Knapp, Agnew and Webster, in letters published in the New York *Medical Record*, under the dates of May 15th, 22d, 29th, and June 12th, to which letters the reader is referred who is desirous of following the matter in detail.

Dr. Evetzky's article is an attempt to show in what manner electricity might exert a favorable influence in the progress of cataract, but the case he cites in illustration fails to support his belief, because at the end of the treatment V. was much worse than at the beginning. It is true V. was at one time found to be better than at first, but the circumstances under which the test was applied are not given. This is an unfortunate omission, since, as Dr. Knapp remarks in one of his communications, persons affected with central cataracts (as in this case) have very variable vision, according as their pupils are larger or smaller under the influence of light.

Optico-ciliary Neurotomy, the proposed substitute for extirpation of a lost and painful eyeball. By J. J. Chisholm. Transactions Medical and Chirurgical Faculty, Maryland, 1880.

Up to the date of publication of the paper Chisholm had done ten operations, in two of which he had to subsequently enucleate, after a lapse of three weeks in one, and of five months in the other.

From the German report on the progress of Ophthalmology for the second half of the year 1879,* we select the following:—

* Translated by Dr. R. O. Born, *A. f. O.*, vol. ix, No. 3.

Dr. H. Magnus, of Breslau, says, in reviewing the book of Dr. Alt, on the "*Normal and Pathological Anatomy of the Eye*," with ninety-five wood-cuts, drawn from his own preparations (Weisbaden. F. Bergmann, 1880, the English edition, by G. P. Putnam's Sons, New York):—

"A compendium of the normal and pathological anatomy, important and indispensable to the teacher as well as to the practitioner. Alt has laid more stress upon the pathological conditions, and less extensively described the normal structures. A great number of most instructive engravings, drawn from nature, by the author, materially increase the value of the book, and facilitate the understanding of the pathological processes. The book really fills a long felt want in our literature, and will greatly contribute to the study of the pathology of the eye."

This book will be found most reliable to those studying the microscopic anatomy of the eye, because from Stricker, etc., the histology can be thoroughly worked up; but we must turn to Alt when we want advice concerning the microscopical examination of a pathological eye. This latter is the information wanted by the surgeon, who is always supposed to be familiar enough with his histology.

Mauthner. *Hemiopia.* (*Vortrag in der wissench. Vers. d. Wiener med. Doct. Coll.*, 24 Mærz., 1879; *C. f. A.*, p. 316.)

"He states, as to the origin and course of the optic nerve fibres: The centres are in the posterior lobes of the cerebrum; from there the fibres pass through the intercalated ganglia: thalami optici, corpora quadrigemina and geniculata; they emerge as optic tracts; until then, without a partial crossing of the lateral bundles, they are partially crossed in such a manner that in each optic nerve the main portion of the fibres comes from the opposite side of the cerebrum."

D'Œnch. *Contributions to the Knowledge of Congenital Ectopia Lentis* (*C. f. A.*, Vol. ix, p. 31), will appear in the English edition of these archives. Careful bibliography. The results are as follows:—

"1. Ectopia lentis is a formative defect, the causes of which are not yet explained.

2. It always affects both eyes, in most cases symmetrically.

3. The dislocation is almost always upward, up-and inward, or up-and outward.

4. Most frequently (about 80 per cent.) the lenses remain clear; they are often smaller than normal.

5. The zonula Zinnii can either be present or wanting.

6. It is connected with myopia in about one-fourth of the cases.

7. It may remain stationary during the whole life, or develop into spontaneous luxation.

8. Heredity plays a part in its etiology."

Dr. John B. Roberts, of this city, contributes an interesting case of "Ectopia Lentis," in the Philadelphia *Medical Times*, January 29, 1881.

We have been recently consulted for a similar case, in which both lenses were symmetrically displaced, and the patient, a lad aged fifteen years, a pupil in the Philadelphia Central High School, was in the condition of a person recently successfully operated on for cataract: *i. e.* without lenses. He used but one eye at a time and saw perfectly with either at 2½″, rubbing his nose on the page as he read, and steadying his hand on his forehead as he wrote. Beyond that distance everything was obscure and imperfect in outline. The adjustment of proper glasses secured for him full distant and near vision, and opened to him a new world.

(*To be continued.*)

Correspondence.

Quinquinia.

Ed. Med. and Surg. Reporter:—

In your issue of February 19th, in the course of an interesting editorial article on the cultivation of cinchona trees, you advert to the fact that in consequence of the abrogation of the duty on quinine, manufacturers in this country are unable to compete with those abroad, and the production of quinine in the United States has fallen off about forty per cent., from an annual average of 900,000 ounces to an average of about 500,000 ounces. "In place of it," you go on to say, "the manufacturers are pushing with vigor substitutes, such as cinchonidia, which is protected by a duty of forty per cent., and the various mixtures of the commoner alkaloids which are rendered at a larger profit than the sulphate of quinine would allow."

I desire, in this connection, to call the attention of your readers to a preparation which, while it contains the other, or as you denominate them the "commoner," alkaloids, cannot properly be called a "*mixture*" of them. This designation is entirely proper and truthful. I believe, as applied to many, perhaps all, of the combinations offered as substitutes for the sulphate, with this one exception. The article to which I refer is offered to the profession under the name of Quinquinia. It consists of all the extractives and alkaloids of cinchona in their natural combination, except quinine, which constitutes about fifteen per cent. of the entire mass.

None of them have been extracted and then re-introduced or re-combined, but they have simply been left in their natural conditions, proportions and combination, and purified in mass from excrementitious, inert and irritating substances.

As you will see by the article which I enclose, and which I had the honor of reading before

the Medical Society of the State of Pennsylvania, at its last meeting, the composition of this residual extract is found, upon analysis, to be very nearly the following:—

Quinia alkaloid,	15 per cent.
Quinidia "	15 "
Cinchonidia "	15 "
Cinchonia "	25 "
Chinoidine "	30 "

It is in the form of a dull brown powder, not crystalline, readily soluble with the addition of small quantities of the acid, and makes up very easily into the pilular mass. It can be furnished at little more than one-third the price of quinine. As an antiperiodic in pure uncomplicated cases of malarial disease it acts quite as efficiently as quinine in the same doses, and has indeed proved successful in many instances in which the latter has failed. My own experience in its use has been rather in diseases of exhaustion, in which I have obtained most satisfactory results from it. The testimony of Dr. L. S. Oppenheimer, of Seymour, Indiana, as detailed in a paper read before the Mitchell District Medical Society of Indiana, and published in the last number of the Cincinnati *Lancet and Clinic*, is worthy of repetition, as the district in which he practiced is one in which malarious diseases are prevalent, and the powers of quinine have been most thoroughly tested. After mentioning the fact that he had, for many years, obtained good results by adding cinchonidia to quinia, he continues: "I have found that from fifteen to twenty grains of quinquinia, administered in five-grain doses every half-hour, the last dose to be given about half an hour before the expected paroxysm, will ward off nearly every simple paroxysm; only in extremely rare cases, when the patient has acquired great tolerance of the cinchona salts, is it necessary to increase the daily quantity to be taken to twenty-four or twenty eight grains."

"In the treatment of night-sweats due to general debility, I have found a solution of quinquinia in an excess of dilute aromatic sulphuric acid quite successful; the tonic properties of the former with the specific action of the latter forming a very desirable union. It is best to give the medicine, whenever convenient, in solution, or in pill form. If the stomach be very irritable, the following elixir will be found to be exceedingly serviceable; most children will take it without any trouble, and it does not produce nausea:—

Quinquinia,	140 grains
Citric acid,	90 grains
Oil of orange,	8 minims
Acetic acid,	30 minims
Spirit of cinnamon,	12 minims
Whisky (or alcohol),	4 ounces
Syrup,	6 ounces
Water,	6 ounces.

"Make a solution of the citric acid in two ounces of the water, with which mix the quinquinia, then add the acetic acid and dissolve; mix the oil of orange and the spirit of cinnamon with the whisky, and add to the other; then add the syrup and water, and filter. Each teaspoonful of this elixir contains about one grain of quinquinia."

"In conclusion, I would repeat that I quite agree with the general expression of physicians who have used this remedy, that it is sometimes apt to nauseate, when taken in large doses, but it does not give rise to other unpleasant phenomena of cinchonism; it *is more reliable as an antiperiodic and tonic than any of the cinchona salts.* (The italics are my own.) It has some antipyretic power, and it is not quite so bitter as the salts. In short, it answers the demand made by the profession of this country for an intelligent arrangement of the useful alkaloids of the calisaya bark, so that the tonic properties should not be sacrificed for the antipyretic, nor the antiperiodic powers sacrificed for the tonic. It approaches nearer to therapeutic perfection than the other preparations of the cinchona tree."

In five hospitals and dispensaries in the city of Chicago, careful notes have been kept of cases of intermittent fever and other malarial affections treated by this remedy, of which the following is a brief synopsis: Intermittent fever, 4; remittent fever, 5; rheumatic fever, 3; neuralgia, 3; gastric fever, 1. In all of these cases the remedy was entirely successful. It was given in doses of from four to eight grains. In twenty of the cases of intermittent there was no return of the paroxysm after the exhibition of the drug. In five, one single chill followed, and in none did they persist longer than a week.

These observations, made with such accuracy as to entitle them to respectful consideration, certainly indicate that we have in this article a valuable addition to our available materia medica. I would especially urge a trial of its virtues upon such of your readers as live in malarious localities.

Benj. Lee, M.D.
1106 *Walnut St., Philadelphia.*

German Measles.

Ed. Med. and Surg. Reporter:—

The presence of numerous cases of epidemic roseola or German measles in this city, or some sections of it, I should say, probably is affording many physicians an opportunity to realize that there is really such a disease. It would seem to be to not a few a total stranger. A somewhat popular practitioner, who received his diploma from our leading medical school a little less than a decade ago, on visiting a person affected with it, declared that he was suffering from some casual disorder of the blood, and on being told that it might be German measles, as a neighboring family had it, pronounced that notion absurd, because there was no disease of that kind, there being only one sort of measles.

There may be something said about this disease in the colleges of late, but I know there was nothing a very few years back; and it is only in the recent text books on practice that accounts of it are to be found. Assuredly it is a distinct affection, and one, too, which it is by no means hard to identify. It resembles both measles and scarlet fever to some extent, but altogether is very different from either. I did not sit down to write a description of it, however, so I will stop here.

T. S. S.

Philadelphia, March 19th, 1881.

Parotitis.

Ed. Med. and Surg. Reporter:—

This, as its name signifies, is an inflammation of the parotid gland, and commonly known as mumps. In Vol. xxxv, No. 18, of the Medical and Surgical Repotrer, I gave the case of Issacher McLane, who lost both parotid glands from suppuration of the surrounding areolar tissue. April 28th, 1880, nearly four years afterwards, I called at McLane's, and found Issacher suffering from mumps. The submaxillary glands were swollen and tender, and the other usual symptoms of mumps were present. The other members of the family were affected by the disease shortly afterwards—those of them who had not previously had it.

I give this to your readers to show that the loss of the parotid glands does not exempt the sufferer from mumps, and that the inflammation is only transferred or attacks other glands when these structures have been lost. We may, therefore, ask the question, Is parotitis a proper name for this disease? J. S. Wright, m.d.

Gatchelville, York Co., Pa.

News and Miscellany.

Report on Trichinæ.

The report on trichinæ, compiled by the late Passed Assistant Surgeon Glazier, of the Marine Hospital Service, forwarded to the Senate by ex-Secretary Sherman, in answer to a Senate resolution of December 13, 1880, is now passing through the press at the Government printing office, and will soon be ready for distribution. The work was commenced in July, 1879, and nearly a year was consumed in the collection of materials. The report contains a history of the discovery of the trichinæ, their natural history, theories of their source, the history of the disease trichinosis, statistics of epidemics, etiology, pathological anatomy, symptoms and treatment, symptoms of trichinosis in animals, a discussion of the means for the prevention of the disease, synopsis of the regulations governing the pork trade in Europe, results of the examination of European and American pork, discussion of some mistakes occasionally made in making microscopical examinations, a statement of the disease as it has occasionally appeared in the United States, and a report of the letters transmitted to the Treasury by the State Department, from United States Consuls abroad, upon the subject. The importance to the United States of having the matter thoroughly understood is shown by the letter of the Secretary of the Treasury, wherein it is stated that "the value of bacon and hams exported from the United States (during the fiscal year ended June 30, 1880) was $50,987,603, and of pork, $5,930,532, and of lard, $27,920.367—in all $84,838,502."

The sections of the report relating to the history of the discovery of the parasite, its natural history and the theories of its origin, are largely compiled from German authorities, original translations of the principal German text-books having been made by Dr. Glazier, as the American literature on this part of the subject was not extensive, the Germans having had more experience with trichinæ and with the disease trichinosis than any other nation. It is shown in the report that nearly all animals may be infected with trichinæ, but the heretofore commonly received opinion that these parasites were originally found in rats is shown to be untenable, although they may be reproduced in any animal feeding upon the flesh of other trichinosed animals, of whatsoever species, and the circle of infection is thus believed to be kept up. The practical "Question of Trichinazation has relation to the infection of man through the hog, and there is not much ground for the supposition that hogs are infected from kitchen slops, as there is nothing essentially different in them from the food eaten by the family." It is further shown that hogs kept in stalls in which trichinosed hogs have been kept will become infected, and that the only means of prevention of this disease among swine is: First, that the stalls or pens in which the animals are kept be kept scrupulously clean; second, the swine must have good, clean food, and not allowed access to diseased meat of any kind—the not uncommon practice of throwing dead poultry, rats or cats to swine shown to be a source of danger, and should be prohibited by statute; and third, as soon as any animal is suspected of disease it should be separated from the herd.

Much space is devoted in the report to the history of epidemics of trichinosis, and it is shown that trichinæ have been found in all countries where search has been made for them, but, owing to the German habit of eating raw meat, there have been more cases of trichinosis in that country than elsewhere. The results of correspondence with the professors of anatomy and demonstrators of anatomy in nearly every medical college and public institution in the United States where dissections are made, are given, and the infrequency of the disease in this country may be fairly presumed from them. These statistics cover the institutions above named, from the New England, Middle, Southern and Western States, including California. A short chapter is added as to the general utility of public abattoirs, and it is reiterated throughout the report that ordinary cooking will destroy trichinæ and render them harmless.

A New Medical College.

The public announcement of the formation of a new medical college in this city was made last week. Its creation has been matter of private conversation for some time. The title is "The Medico-Chirurgical College of Philadelphia." The prospectus says: "Feeling that there is now a demand for another medical school in our city, the founders of the Medico-Chirurgical College join the sister colleges of the regular school in the laudable work of maintaining for Philadelphia her reputation as the chief medical centre of the United States."

A novel feature is a collateral course on English Science and Literature and the elements of Latin, without additional expense to the studen

A three years' course is to be obligatory, in spite of the failure of Bellevue to sustain one.

The college building is at the corner of Broad and Market streets. The following are the officers and faculty:—

Officers—President, Geo. P. Oliver, M.D.; Secretary, Charles L. Mitchell, M.D.; Treasurer, Geo. E. Stubbs, A.M., M.D.

Faculty—Geo. P. Oliver, M.D., 936 North Fifth street, Professor of Principles and Practice of Medicine and Clinical Medicine. H. Earnest Goodman, M.D., 1427 Chestnut street, Professor of Principles of Surgery and Clinical Surgery. Geo B. H. Swayze, M.D., 1828 Columbia avenue, Professor of Obstetrics and Gynæcology and Clinical Gynæcology. Geo. E. Stubbs, A.M., M.D., 1501 North Seventeenth street, Professor of Anatomy and Clinical Surgery. William F. Waugh, A.M., M.D., 878 North Sixth street, Professor of Materia Medica, Therapeutics and Clinical Medicine. A. S. Gerhard, A.M., M.D., 731 North Sixteenth street, Professor of Physiology and Medical Jurisprudence. Charles L. Mitchell, M.D., 839 Race street, Professor of Medical Chemistry, Toxicology and Sanitary Science. Frank O. Nagle, M.D., Demonstrator of Anatomy and Curator. Geo. B. H. Swayze, M.D., Dean.

Pigs as Drunkards.

The *Journal of Science* says, in a recent issue, that two French physicians have experimented with alcohol in pigs. Pigs were chosen for the experiment because of the close resemblance of their digestive apparatus to that of man. The pig who takes absinthe is first gay, then excitable, irritable, combative, and finally drowsy; the pig who has brandy mixed with his food is cheerful all through till he falls asleep; the rum swilling pig becomes sad and somnolent almost at once; while the pig who takes gin conducts himself in eccentric ways; grunting, squealing, tilting his head against the sty door, and rising on his hind legs as if to sniff the wind. Dr. Decaisne, describing these experiments with intoxicated swine, remarks, in the *France*, that they are none the worse for their year's tippling.

Trichinosis Cases.

Several severe cases of trichinosis have occurred in Hoboken, under the charge of Dr. Kudlich. One woman died and her husband was seriously ill. The usual cause, trichinous pork, led to the disease. Another alleged case, in New York city, was said to have been traced to foreign-made sausage. One of our western exchanges records that Mr. Charles L. Ibach, of Indianapolis, died on the 20th, after suffering for eleven weeks from trichiniasis. No doubt for every case recognized, fifty are not.

A Cremation Society.

A cremation society has been organized in New York city. The members are evidently men who are resolved to go ahead, and we are much mistaken if they will not fill a much larger place in the public eye than now seems likely. On the evening of March 24th a large meeting of the members and others was held in the Cooper Institute. A large number of army and navy officers were elected to membership, and an able lecture was delivered on the disposal of the dead, it being a strong plea for cremation.

Sale of Poisons.

Three cases of serious poisoning, by mistakes of druggists, have occurred in New Haven in two weeks' time. One resulted fatally. Similar cases are reported from different parts of the country quite frequently. It is an illustration of the carelessness with which medicines are often dispensed.

Personal.

—"Dr." Francis Tumblety, known throughout the United States and Canada as "the great Indian doctor," has come to grief in New Orleans, for picking the pocket of a Government clerk.

—An alleged "confession" by the notorious diploma vendor, Dr. Buchanan, has been published; its chief aim is clearly to drag others into the mire with himself.

—Dr. Joseph F. Edwards, of this city, has taken the editorial charge of the *American Specialist*, published by Presley Blakiston. He is already known as a medical author, and no doubt the *Specialist* will have a prosperous career under his management.

Items.

—We omitted to mention that the "Easiest Way of Housekeeping and Cooking," reviewed on page 296, is published by Fords, Howard & Hulbert, New York city.

—From recent statistics collected by M. Lunier, there are 33,225 epileptics in France. Of these only 3550 are in hospitals. He urges that were a larger number under hospital treatment, cures would be more frequent.

—Senator Bayard, of Delaware, says: "So far as my experience goes, a well-regulated system of license, whereby revenue is largely brought into the public treasury, coupled with severe penalties for illicit sale, has proved the most efficient check upon the abuse of the liquor traffic"

—Last month a banquet was given by many of the leading citizens of Bristol to the Hon. Theodore Canisius, M.D., who, after six years' residence there as United States Consul, was about to leave the city. At the conclusion of the banquet an address was presented to Dr. Canisius, signed by the Mayor of Bristol and several of its more influential inhabitants.

—Labouchere, the editor of London *Truth*, says that English physicians and English mothers are behind those of America and the south of Ireland in not vaccinating children above the ankle instead of on the arm, which is so frequently disfigured. What Labouchere does not know about medicine and surgery is (in his opinion) not worth the knowing.

—"Pig butter," or "suine," is extensively manufactured in the West, and packed and sold to the unwary purchaser as a genuine cow product. It is composed of 75 per cent. of lard, and is said to contain fatty acids injurious to the health. Trichinæ may also be present. The attention of the Philadelphia Board of Health has been called to the matter.

—The prescription below was actually sent to a Louisiana drug store to be filled, and that by a man who pretended to be a physician :—

FOR BOB SMITH'S CHILD.

℞.		
	Iodine,	j ℥
	Castoroil,	j ℈
	Watter,	ij ℥.

Put into quart bottle and give a tablespoonfull four times adayy.

The druggist declined to fill it.

—The following resolution has been unanimously adopted by the Hale County, Alabama, Medical Society :—

Resolved, That the members of this Society establish a list of names, to be known as the "Black List," and that no physician in good standing go to see or prescribe for any one placed on said list unless he pay cash or give ample security, and that each name remain on "Black List" until removed by the physician who placed it there.

OBITUARY NOTICES.

DR. ISAAC RAY,

Well and widely known as a writer on the treatment of insane patients, died March 31st, at his residence in this city, in the 74th year of his age. He was born in Beverly, Maine, and graduated at Bowdoin College in 1827, and studied medicine with Dr. Shattuck, in Boston. He practiced for some time in Portland and Eastport, and then took charge of the insane asylum at Augusta. Subsequently he was in charge of the Butler Hospital at Providence, and came to Philadelphia in 1867, since which time he has been engaged as a consulting physician. In July, 1880, he was elected an honorary member of the Medico-Psychological Association of London, and received the diploma a few weeks since. He had been in ill health for twenty five years previous to his death. He was elected a Fellow of the College of Physicians of Philadelphia in 1868.

Dr. Ray was a voluminous writer on medical subjects, and included in his works will be found: "Conversations on Animal Economy," 1829; a treatise on the "Medical Jurisprudence of Insanity," 1838, a work termed by Mr. Cockburn, Attorney-General of England, as "perhaps the most scientific treatise that the age had produced on the subject of insanity in relation to jurisprudence;" "Homicide—Epilepsy," 1867, a review of the case of G. W. Winnemore, executed for murder at Philadelphia, August 29th, 1867. He also contributed papers to the *North American Review*, *American Quarterly Review*, *Christian Examiner*, *American Jurist*, *Law Reporter*, *Boston Medical Magazine*, *American Journal of Insanity*, and the *Atlantic Monthly*. The eleventh edition of his "Medical Jurisprudence" was published in this city in 1860.

RICHARD HENRY LEE, M.D.,

Died, March 22d, after a long illness, in the 54th year of his age, at his residence in this city. Dr. Lee was a successful physician. He was descended from one of the collateral branches of the family of Richard Henry Lee, one of the signers of the Declaration of Independence, and his father, Dr. Ralph Lee, was a well-known practitioner of Bucks county.

Dr. Lee studied medicine at the University of Pennsylvania, and located in this city, where he soon became most favorably known. He was devoted to his profession, and, though he never aspired to play a prominent part before the public as a professor or writer on medical subjects, he was recognized among the faculty as a man of solid attainments. His complaint was Bright's disease, and for some time prior to his death he had retired from active practice.

QUERIES AND REPLIES.

Dr. J. W. C., of Ala.—1. Green German Soap (Hebra), costs fifty cents per pound. 2. We will accept postage stamps for our publications, but don't prefer them.

Subscriber, Kansas.—Lemon grass is the *andropogon citratum* We cannot find any oil from it mentioned, nor has its medical properties been defined, although it is included in some catalogues of medicinal plants.

MR. EDITOR.—I wish some of the many readers of your valuable journal would give me the best formula or recipe for disguising the intense bitter taste of sulphate of quinia in solution.

Also the best treatment for preventing the return of intermittent fever, known along the Schuylkill valley as *ague*, which in some cases returns in seven, fourteen or twenty-one days, and some still shorter periods, every few days. S. S. F.

Pennsylvania.

ED. REPORTER.—I find in your issue of March 19th an article or lecture by Prof. Pepper, on the subject of Œlema, in which he makes the following statement, "but in Bright's disease we have the upper parts of the body affected before the lower."

I would like to ask the lecturer if he lays that down as an absolute rule? D. H. WOOD, M D.

Quincy, Mich., March 2 th, 1881.

Drs. J. C. W. and G. E. S.—The formulæ are—

LIQUOR HYDRARGYRI BICHLORIDI—VAN SWIETEN'S LIQUOR.

℞.			
	Hydrarg. bichlor.,		gr. x
	Ammon. mur.,		gr. x
	Aquæ destil.,		℥j. M.

DOSE.—℥ss-℥ij.

The American Medical Formulary (J. J. Reese, M.D.).

MIST. RHEI CUM GENTIANÆ.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combinat on, the proportions of each constituent may vary somewhat. according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

PNEUMONIA—NO. IV.

BY HIRAM CORSON, M.D.,
Of Conshohocken, Pa.

(*Continued from page* 263.)

Since my articles have appeared in the Reporter, I have received from some of your readers letters thanking me for what I have written, and presenting some cases of their own, which are well worth publishing, as evidence of the widespread fear to deplete a patient in a recent acute attack of inflammation of the lung; as evidence too of the good results produced by depletion by drawing blood, in such cases, and as evidence of the mortality following the treatment recommended by *some* teachers in our medical colleges, who rely on the aconite, veratria, digitalis, carb. ammonia, and stimulant and stuffing treatment.

Dr. W. B. T., of Paris, Texas, writes: "I have just read with great pleasure your several articles on pneumonia, and I am glad to find you laboring to restore 'the lost art,' in the treatment of that disease. At the last meeting of the 'North Texas Medical Association' I read an essay (by appointment) on the above disease. I said that blood-letting was the remedy par excellence in sthenic pneumonia, and in all cases where I felt certain of the proper time, and in many cases where I felt uncertain, I am now satisfied that the patient might have been better off in other hands. Had I remembered one sentence in Watson's Practice, I might always have known the proper time, viz: "never bleed for the extravasated products of inflammation." The period of engorgement is of variable duration, and that exact time is any time between the reaction from the chill to the beginning of the second stage. Sometimes the congestion involves so great an amount of lung tissue that great weakness and prostration are manifested from the beginning; in which condition nothing is so effectual as a free bleeding.

"The association fought me hard on the blood-letting, in which fight the fact was developed that several old practitioners, and of some notoriety, had never bled or blistered a patient laboring under any disease, or condition, in all their professional career.

"To my mind, aconite and veratrum were questionable rivals of the lancet from the beginning; the former always a dangerous dose and of very little account in anything, and the latter greatly overrated in everything. I am glad that you have taken up your pen again, as one page from an experienced observer is worth more to a young practitioner, if he will heed it, than volumes of the labored, far-fetched fume and froth of the latter-day saints, whose practice might be termed a sort of sickly sentimentality, that amounts to less than nothing."

It will be found, by those who will take pains to observe, that many of those who oppose blood-letting are like the old doctors spoken of above, who had never bled a patient in any disease.

Dr. J. H. B., of Cook county, Illinois, writes: "I hope that I may read more of your remarks on pneumonia, as I consider them of much value to myself, being founded on long experience. I can well remember two particular cases of pneumonia that occurred in my ward while acting as interne in the City Hospital, Boston. One, a robust young man, on expectant treatment, with

diet, etc. etc., which was followed persistently. The result was unsatisfactory—extremely so. The other case—in brief—a slender boy of twelve or thirteen years of age, with whom the ordinary routine treatment was given. At midnight I was called, with the information that he had suddenly grown worse. I found him with respiration very much increased, pulse very rapid and somewhat strong, face suffused, and somewhat delirious. Not being a bleeder, I did not bleed, yet I suppose a kind of instinct prompted me to do the next best thing, and so I cupped him well on the back and side of the chest. On my visit next morning, as I was passing down the ward, he cocked his head up and grinned all over at me, and when I went to his bedside, he asked me, with a smile on his face, 'Doctor, can't I go to work to-morrow.' He felt well, and soon fully recovered. That boy twelve hours before was in a dying condition, and without depletion he would have died. I have waited to hear somebody speak intelligently in regard to bleeding, which, so far as I knew, seemed to have fallen into obscurity. I believe in the faith of our fathers, and would consider it a favor if you would continue to give us your experience. Our fathers knew something (although this micro-physiological generation of physicians is very wise), and I shall be glad to have your experience on other subjects, as well as on that of pneumonia."

W. C. W., M.D., writes, from Sandy Hook, Conn.: "I cannot refrain from thanking you personally for your firm stand in reference to the treatment of pneumonia by blood-letting. Since your first letter was published, I have treated three bad cases after your plan, with *perfect* success in every case. One was an old man of seventy-eight years. I had to work hard to get them to consent, but I finally bled him freely and saved his life, I am assured. Pneumonia in this section is very fatal, with the cold weather, and it really made me sick at heart to be called to a case; but now I feel that I have a weapon equal to the foe. I am under many, many obligations to you, and only hope you will have a reprint sent all over the land."

Dr. J. C. S., writing from Three Springs, Pa., says: "I have been very much interested and instructed by your papers on pneumonia in the Medical and Surgical Reporter. Pneumonia is considered very fatal here, especially among the aged. We never bled our patients. I heard Dr. Gross, four years ago—while attending lectures at the 'Jeff'—recommend blood-letting in pneumonia, and heard Dr. Da Costa condemn it. As the latter was supposed to be authority 'on practice,' I chose to follow him. My preceptor used blisters and tartar emetic, and I have seen good results and some failures from their use. I saw, with a neighbor physician, just before your first article appeared, a stout, hearty man go down in five days, in spite of aconite, blisters, carb. ammonia, poultices, and all the stimulants that could be got into him. I then thought I would try the lancet—although I never had any instruction in its use—and thus far have bled six patients in pneumonia. In two of them there was complete cessation of all untoward symptoms following venesection. The other four passed on to the second stage, but are convalescent; two of the four were old ladies, one 65 years, and of slight frame. I think your suggestion of bleeding late saved one of those old ladies. It was the third or fourth day of her illness when I found her insensible, gasping for breath, absence of any respiratory sound over entire right lung, left lung partly engorged, bronchial râles, and all signs of complete engorgement. It was a case of which I would ordinarily have said, 'it will die in six hours.' But I had her supported in bed, and then bled her freely. She became relieved immediately (all the cases have experienced decided relief), and slept soundly that night, and the next day I found her much better; has done finely since. I am not writing to give you an account of my limited practice, but to thank you for your service to me and to my patients; also, if you have not made up your mind what part to consider next, I would suggest to you to take up *the treatment of pneumonia in children.* I hope my suggestion is not out of place, as I think you will have great trouble to convince the profession of the propriety of bleeding children, although willing to try it on adults."

Dr. D. W. K., of Allegheny City, writes: "Your article on pneumonia and its treatment meets with my hearty endorsement, and I congratulate you upon having written so clearly and intelligently upon so grave a disease."

Dr. J. G. C., of Kittaning, writes: "I have just finished your last article on 'Blood-letting in Pneumonia,' in the Medical and Surgical Reporter. I am a practitioner of fifteen years' standing, and do not bleed except in a few cases. I am satisfied I do not bleed often enough. I have seen the great benefit derived from it. I write you this short letter to thank you, in the name of the Armstrong County Medical Society, for the firm stand you have taken on this subject, and also as to the natural delivery of the placenta and on natural delivery."

Dr. R. L. M., of Spring Valley, Minnesota, says, on a postal card: "Your articles on Pneumonia, in the REPORTER, were read by me with great interest. I believe in your words. I am sure that I have lost patients because I did not treat them as you direct, but followed the rule we were taught. * * * Give us other articles."

A very prominent physician of this State writes to me: "I have read with great pleasure your articles on Pneumonia, in the REPORTER. The only point that I would hesitate about would be the ice-bag. I am attending now a young man with pneumonia of lower half of left lung. On Sabbath I bled him till he roused out of his stupor and sleep, and put a blister on his side—a slow one—and gave him purgatives and expectorants. Yesterday he was doing well: pulse 116; temp. 105°; delirium subsiding; sputa free and bloody. I have not had a large experience of this disease, but have never lost a case. My neighbor loses cases frequently, of very stout people; he neither bleeds nor blisters. *I* say, bleed, blister, and give purgatives and expectorants immediately."

Dr. Amos Seip, of Easton, Pa., says: "Though past the midnight hour, I cannot retire without expressing to you my hearty thanks for your timely article in the REPORTER, on the treatment of pneumonia. I think it is high time that the much-abused instrument, the lancet, shall be again carried in the pocket and used in the treatment of acute inflammatory diseases. The idea that diseases of the present day will not bear depletion as well as they did thirty or forty years ago, is preposterous. It is a mere whim; a blind following of the miserable, French, expectant plan, that so many of our modern teachers have adopted in the treatment of pneumonia, etc. I have been in practice more than thirty-two years, yet have never given up the use of blood-letting in acute diseases, especially those of the chest, brain, etc. It is absurd, if not criminal, for a physician to allow an attack of pneumonia to go through its three stages, if called early. No, I agree heartily with you; not only is blood-letting well borne in acute diseases, but also that, with the adjuvants, it is the only rational treatment. It is sad to take up the public prints and read of this and that noted man, "died of pneumonia." But is it any wonder, when such pernicious doctrines are promulgated by those whose office it is to teach young men—hundreds of whom leave our colleges not only untaught in the use of the lancet, but prejudiced against it by their teachers? No! a thousand times No! The day must come, is coming, when they will see the unfortunate results of this modern heresy. Now, a word on my own experience; for, after all, one severe attack of disease in a physician's own person is worth all the theory in the world, so far as practice is concerned. Some nine or ten years ago I suffered from a severe attack of pneumonia. I had been exposed, in rough, November weather; the symptoms gradually increased in intensity; there was high fever; respiration above 30; pulse 120; sputa tough and rust colored, with severe pain; in short, all the symptoms of an exaggerated attack. I could compare the pain felt at each respiratory effort to nothing else than that which would be produced by a jagged knife thrust into the side. I stood it for about eight hours, then sent for my friend, Dr. Traill Green, who, unfortunately, was not at home. Before daylight I said to my wife, 'this is simply death itself, if relief be not soon had; get my lancet, the bandage, etc.; when I cut the vein let the blood run till I show signs of faintness.' As the vein in the left arm did not develop well, I was compelled to use the left hand and bleed from the right arm. Never shall I forget that night. With the instrument in my left hand, I let fly; the blood flew; took sixteen ounces before the desired effect was produced; then fell over on the bed. I breathed freer immediately; a grateful perspiration bedewed the surface; all the symptoms were moderated, and next morning, when Dr. Green arrived, finding me much better, he advised to continue the medicine I was using, and left, promising to call again. I indulged too much, that afternoon, in conversation with medical friends; at any rate, by night all my pain, and fever, and difficult respiration returned. Dr. Green came in and bled me another pint, and again I felt easier; and that bleeding, with the ordinary treatment of thirty years ago, 'broke up,' as Dr. Green said, one of the most formidable attacks of pneumonia that either of us had ever seen. The peculiar *weakness* that you speak of I well remember. Never shall I forget it. One such an experience is worth all the weak, timid, do-nothing theories and practice in the world. What, let me ask you, would have been the result if we had let it alone and turned our attention to the liver and kidneys? It would require no prophet to tell the result. The modern notion that aconite, veratria, digitalis, etc.—and yes, the poultice—will supersede the lancet is sheer nonsense. I would be ashamed to look a family in the face, if I were to lose a father or son. ill with pneumonia, and had failed to use it."

There are a number more postals and letters lying before me, which have been sent to me to express approbation, by the writers, of the views I have expressed; but they must be passed by for the present.

These extracts confirm the truthfulness of the statements made by me in reference to the value of the lancet, and testify, like voices from the grave, of those dead prematurely from erroneous treatment. As I write, my eye falls on a postal received but yesterday, from which allow me to quote—so appropriately does its confession come in here: "Your articles on pneumonia are just excellent in theory, and in practice, doubtless, would be found as you claim. Many cases of the disease die in the ——— hospital; some of sthenic forms, which, I doubt not, might have been saved (?) I am going to possess a lancet before many days, and use it when opportunity presents." He had served in a Philadelphia hospital; a young man of fine abilities, a profound student, sent from a medical college ignorant of even the *art* of bleeding, then serving for a year or more in a hospital, and there seeing men die of pneumonia, while his "Chief" was denouncing the only remedy which could have saved them. How sad! And yet, how much more sad is the reflection that this very year there have been hundreds sent from the colleges ignorant as he was of the value of venesection and the mode of using the lancet, and ready to take on themselves the treatment of this disease by means recommended by theoretical teachers, who are searching for something new which may hereafter be associated with their names. With your permission I shall continue this subject.

In closing this paper, I feel that I ought to apologize to the authors of the above letters, for having—through fear of being charged with a desire to magnify myself—shorn them of the enthusiasm, the thankful and grateful feelings under which they were written, and which testify so strongly of the sense of duty which impelled them to write on this subject. Here, too, I may properly refer to an error which slipped into my first paper, namely: Speaking of Bayard Taylor dying of pneumonia, when I knew very well that he died in Germany, of another disease. I intended to name Thomas Buchanan Read; the substitution of the one for the other was an accident. For many years I had admired the writings of these two highly gifted men, so dear to the people of eastern Pennsylvania, and in my mind always intimately associated. Was it strange, then, that, in my hurried way of writing, I should have put the name of him—

"Whose latest verse
Was a garland on his hearse,"

in the place of his whose genius gave to us, as part of its creations, the "Autumn Scene" and the "Spirits of the Waterfall?"

THE HYGIENE OF OLD AGE, WITH SPECIAL REFERENCE TO PROSTATIC HYPERTROPHY AND SECONDARY DISEASE OF THE BLADDER.

BY REUBEN A. VANCE, M.D.,
Of Cincinnati, Ohio.

Read before the Cincinnati Academy of Medicine.

The subject chosen as a text for my remarks this evening is one that can be treated in part only on such an occasion as this. I have, therefore, determined to limit my remarks to the indications and effects of prostatic hypertrophy, and the steps to be taken for its relief. Curtailed as is the subject by these restrictions, it is, nevertheless, too voluminous for thorough treatment in the time at my disposal. Therefore, if I but outline to you a few of the more important facts bearing upon senile enlargement of the prostate body, and review such of the morbid anatomical conditions of the urinary apparatus as I deem of interest in this connection, and then allude to the method of relief I consider of vital importance, I shall accomplish all I think it advisable to attempt.

The normal prostate, let me premise, is shaped like a chestnut, and, longitudinally, is an inch and a half from base to apex, one and three-quarters transversely near the base, and seven-eighths of an inch in thickness at the latter point, while in weight it is from four and a half to five drachms. Now, while marked excess in either measurement or weight denotes hypertrophy, alteration in form is a far more certain criterion by which to judge. Nevertheless, there are many cases in which bladder-disease developes as a consequence of senile enlargement of the prostate, in which physical exploration fails to yield any evidence of increased bulk or modified form on the part of the prostate body.

Sir Henry Thompson, who, conjointly with Dr. Messer, dissected the prostates in about 200 subjects over 55, found that about one in three exhibited some enlargement of that organ, but only one of these out of seven had had symptoms of the complaint. According to Thompson, the period of life between 55 and 65 is that during which the affection most commonly begins to be developed. He has never met with an instance of hypertrophy of the prostate at so early a pe-

riod as 50 years of age, while on the other hand he says it appears rarely to commence after 70, and is exceptional after 80 or 85. He thinks that the man who has escaped enlargement of the prostate at 65 will never be troubled with it. In senile hypertrophy there is an augmentation of the muscular and connective tissues of the prostate, with little, if any, increase of the glandular element. There is increase of volume, weight, and density, with modification of form. The enlargement may be general or partial.

Common as is prostatic hypertrophy, and well defined as are the symptoms accompanying its advanced stages, there are few affections more obscure in their early manifestations. A few months ago a well-known gentleman of this city stopped me on the street with the remark that he had been intending to call and see me for some time; that his kidneys were troubling him, and he wanted something that would relieve the distress from which he was suffering. A question or two speedily revealed the nature of the case. For months he had been compelled to get up two or three times of a night to relieve his bladder, and he was now conscious that each act of micturition, although prolonged and difficult, was of little avail so far as a free evacuation of the urine was concerned. The urine was clear; it never had contained blood; but there was, at the time of my first interview with this patient, an almost constant call to urinate, and each act freed but a small quantity of urine. No amount of explanation sufficed to make him appreciate the true nature of his case. He had an all-sufficient explanation for the phenomena troubling him so greatly; this was, "irritability of the bladder," alternating with "congestion of the kidneys." If the nature of senile enlargement of the prostate was spoken of, and the fact that his age—he was in his 49th year—predisposed him to it. and, furthermore, if his attention was called to the fact that the frequency of micturition from which he suffered was due to retention and repletion—a morbid degree of retention of urine, owing to his inability to evacuate more than a small quantity, thus leaving a certain amount of residual urine in the bladder, which increased week by week—he was sure that the contrary was the case, for he knew that he was passing more water than usual. According to his view of the matter—one supported by the authority of his family physician—his kidneys were congested enough to cause hyper-secretion of urine, and his bladder was so irritable that it would retain but a few tablespoonsful at a time. To try to make this patient believe that his bladder was water-logged, so to speak, that he was carrying about with him from a pint to two quarts of water, each act of micturition but discharging a gill or so of urine, the organ never emptying itself completely, but on the contrary gradually falling into a diseased state from the continuance of the unnatural conditions under which it was placed, was mere waste of time. The last act in the preliminary stage of this case occurred within ten days of the interview referred to. He called and announced that something must be done for his relief, for he was in a deplorable plight; that his bladder, "which had been so irritable as to retain but a small amount of urine at a time, for months," had now utterly failed him; that for a week water had been dribbling from him at night, while sleeping, while for the last forty-eight hours it ran away from him, drop by drop, sleeping or waking. Upon passing a catheter, twenty-s ven ounces of urine were withdrawn; finding the bladder distended still, the catheter was removed, and the patient informed of the necessity for prolonged treatment.

This patient's experience is typical of that of many who suffer from this complaint. In the very beginning the individual may be conscious of nothing but an unusual degree of reluctance—if I may so express it—on the part of the bladder to part with its contents. The patient experiences a call to urinate; he places himself in position to respond to nature's demand, but so soon as he does, the power of the bladder to empty itself seems temporarily impaired. The experienced surgeon sees in this condition the influence of an abnormal prostate; far different is it with the patient. Without he, by chance, secures competent professional advice, the patient never knows the true nature of his disease, or even that it is a disease, until the condition of his bladder forces him to seek surgical aid. A want of power to promptly empty the bladder, in a man between fifty and sixty years of age, almost invariably indicates prostatic enlargement. If, in addition to this delay in emptying the bladder, there is either an increase in the frequency of the calls to urinate, or a diminution in the quantity of urine passed, this condition is denoted. Frequency of micturition, a diminution in the quantity of urine voided, a failure or marked impairment of the individual's ability to empty the bladder promptly and satisfactorily, indicate commencing obstruction from senile enlargement of the prostate. In a word, when a man beyond forty-five years of age experiences an increase in the frequency of his calls to empty the bladder, or has his attention drawn to that

organ by a delay in emptying it, or an inability to accelerate the flow of urine after it starts, he should suspect prostatic hypertrophy.

The anatomical condition accompanying prostatic hypertrophy, preventing complete evacuation of the bladder, is very simple and quite devoid of all danger, provided proper hygienic measures are adopted from the first. In the beginning but a minute amount of urine may remain in the bladder. It is not improbable that, in many cases, accident initiates this condition. In order to empty the bladder, time is necessary. Circumstances which prevent the patient giving the requisite attention to this function may be the means of developing secondary disease of the bladder. A patient with commencing hypertrophy of the prostate—a lawyer—was engaged in an exciting trial, and the day he addressed the jury he neglected the proper evacuation of his bladder; that night the urine dribbled away while he was asleep; the next morning, upon passing a catheter, I discharged a quart and a half of urine and found the bladder completely atonied. If individuals suffering from senile enlargement of the prostate could be made to appreciate the fact that the mere hypertrophy of that organ is a matter of secondary consideration, while the condition of the bladder is of vital moment, fewer sad cases of secondary vesical disease would be encountered.

I have said little, as yet, of that condition in which these cases all result: distention of the bladder with overflow of urine. Every surgeon knows but too well how commonly these cases are mistaken for the very opposite state; how the sufferer will argue that he cannot have anything but incontinence, for the self-evident reason that he is constantly passing water. Yet, in truth, his condition is but the final stage of the cases to which I have been alluding. Day by day, and little by little, there is a slow accumulation of urine in the gradually distending bladder. At first the patient, finding it tedious to stand in the water-closet and completely empty his bladder, discharges only enough to relieve himself for the time. The ounce or two of urine thus left by negligence may not be voluntarily voided at the next act; in this way the seeds of urinary decomposition and bladder disease are planted. In one case the quantity of urine increases from day to day, until, finally, the bladder becomes full and its walls atonied; in another case the retained urine undergoes decomposition, and inflammation of the lining membrane of the bladder is induced; in both, the resulting disease can be traced to the neglect of complete evacuation of the bladder. Strange to say, if the practitioner is careful to save and measure the urine daily passed by such a patient, the amount voided in the twenty-four hours will be found fully equal to the ordinary discharge of a healthy individual in the same interval of time. It does seem as if the local irritation had some effect in increasing the quantity of urine secreted; this is especially true as regards the night as distinguished from the daytime. Such a patient will be compelled to get out of bed and use the night-vessel from five to thirty times between bedtime and morning. While the amount voided on each occasion may not be large, yet upon taking the whole quantity discharged in the twenty-four hours and comparing it with that usually passed daily, in health, there will be no material difference. This partially explains the incredulity of certain patients when informed of the nature of their disease. Any intelligent man can understand his surgeon when the latter tells him that his bladder is irritable and impatient when but a minute amount of urine is present; that his frequent calls to micturate and trouble in emptying the bladder arise from vesical irritability and urinary incontinence. Quite different is it when an endeavor is made to explain the complex conditions arising from prostatic obstruction, muscular atony, and vesical catarrh. The patient shrinks from an instrumental examination, and is loth to have a catheter introduced, even for diagnostic purposes.

Yet, upon the proper employment of this last instrument depends the prevention of secondary disease of the vesical cavity in individuals suffering from prostatic enlargement, and the relief of those patients who have been so unfortunate as to have atony of the muscular walls, or catarrh of the lining membrane of the bladder ensue as a consequence of prior disease of the prostate body. Just so soon as an individual of the male sex, who has passed his forty-fifth year, finds himself compelled to micturate more frequently than usual—especially at night, and under circumstances excluding obstructive disease of the urethra—surgical advice should be taken, and a catheter employed. If a catheter is then passed—and it should be used immediately after the patient has voided all the urine he can voluntarily discharge—and a quantity of residual urine wi h-drawn, the surgeon has an unmistakable guide both as to diagnosis and treatment. That process of urinary retention has been inaugurated, which, if not relieved, will certainly result in either atony of the vesical walls and indefinite

distensibility, or in contraction of the bladder and partial hypertrophy of the muscular layers. The details of the measures which should be adopted in connection with the use of the catheter in these cases I need not dwell upon; suffice it to say, that a few weeks' judicious employment of that instrument will relieve even the most unpromising cases, and permanently cure the majority of patients with commencing bladder disease. I shall also dismiss, with a word, the danger attendant upon the injudicious employment of the catheter. Sir Benjamin C. Brodie long since pointed out a peculiar class of patients in whom the complete evacuation of the urine by the catheter, at one time, was apt to be followed by serious results. This danger can always be obviated by removing but a part of the residual urine at any one time: in order to do this, the catheter should be introduced and the bladder but partially emptied twice a day, for three days. The point upon which I desire to lay special stress, is the necessity for immediate resort to the catheter so soon as the early symptoms of prostatic obstruction declare themselves, and its use sufficiently often thereafter to empty the bladder at least once daily, and thus prevent urinary accumulation and vesical disease. By adopting this course the great number of cases of bladder disease in old men may be reduced to the minimum, and the profession afford most efficient service in advancing the hygiene of old age, with special reference to those secondary affections of the vesical cavity which have their origin in prostatic hypertrophy.

TWO CASES OF PULMONARY SYPHILIS.

BY CARL SEILER, M.D.

Read before the Philadelphia Laryngological Society.

So little is known about pulmonary syphilis or syphilitic phthisis that I feel prompted to put on record two cases of the affection which came under my notice during my recent sojourn in Jacksonville, Florida.

Case I.—Mr. M., æt. 26, had been sent south to spend the winter, being, as was supposed, afflicted with tuberculosis. When he consulted me he complained of a harassing cough, with copious expectoration, which was tenacious and of a yellowish-greenish color, frequently tinged with blood; great dyspnœa, hoarseness amounting almost to aphonia, and difficult and painful deglutition, the pain during the act of swallowing being most severely felt in the left ear. He was very much emaciated and feeble, but had no night sweats. He stated that the trouble commenced about three months previous, with cough, loss of appetite and flesh; that he had taken various remedies, but without relief, and that he had finally been advised to go south. He had been in Florida for several weeks, but felt discouraged, as he had not only not improved, but that his throat had become worse. On physical examination of the patient's chest, which was well developed, I found the usual signs of infiltration, but most marked in the middle and lower lobe of the right lung, while the apices of both lungs were almost free from any disease.

On inspection of the throat, I found the following condition of the parts: The soft palate was hyperæmic and somewhat relaxed, the uvula slightly elongated, and at the free edge of the velum I noticed two sharply-defined bands of inflammation, extending from the anterior pillars to within a short distance of the root of the uvula. The posterior pillars were intensely red and showed two small elongated ulcers, one on either pillar, symmetrical both in shape and position. The pharynx was dry, red, and its follicles enlarged. With the laryngoscope the epiglottis was seen to be very much thickened and of a horseshoe shape, with an ulcer extending almost over the entire free margin of the organ. On account of this swelling the interior of the larynx was obscured, but I could see enough to detect an ulcer on the left arytenoid cartilage, extending into the inter-arytenoid commissure.

The ulcerations in the throat might have been explained by supposing them to be due to tubercles, yet the symmetrical disposition of the ulcers on the posterior pillars, the sharply-defined lines of inflammation on the free margin of the velum palati, and the absence of the ashy-gray discoloration of the mucous membrane, which we always observe in phthisis, made me suspicious that the case might be one of laryngeal syphilis. and that perhaps the lung disease might be due to the same cause. I therefore questioned the patient as to a previous specific history, but could not obtain any satisfactory answer. The patient stated that he had had an attack of gonorrhœa four years previously, but had had no skin eruption or swelling of the glands; his throat had been sore on several occasions, and he suffered from rheumatic pains in his limbs, especially at night. He stoutly denied ever having had a chancre. In spite of this rather unsatisfactory history, I decided to put the patient on antisyphilitic treatment. I accordingly gave him ten grains of iodide of potassium three times a day, together with cod-liver oil, and as much other nourishing food as he could swallow. I also or-

dered inunctions of cod-liver oil over the chest and back, and had his arms and legs washed with whisky night and morning. The ulcers I touched with iodized glycerine, of the following composition: iodine, grs. 5; iodide of potassium, grs. 30; glycerine, fl. ℥j; washing off the thick coating of pus first with a solution of bichloride of mercury, 1½ grs. in glycerine and water, each two ounces, thrown into the larynx by means of an atomizer.

Under this treatment the patient rapidly improved; his dyspnœa diminished, deglutition became less painful and difficult, he gained strength and flesh, and was able to walk a considerable distance without undue fatigue, two weeks after the treatment had been commenced. The ulcerations in the larynx gradually healed, and, although considerable loss of tissue resulted, yet, after four weeks. he was able to swallow without discomfort. A physical examination of his lungs, about this time, showed still some dullness over the middle and lower lobe of the right lung, while the left lung and the apex of the right one seemed entirely free from disease. When last seen the patient was progressing as well as could be desired, and considered himself almost well.

Case II.—Isaac S., a negro laborer, aged 30, consulted me about a persistent and at times violent cough, shortness of breath, and loss of strength and flesh. He also complained of soreness of the throat and great dryness of the fauces. He stated that he had first noticed any trouble about three months before, and attributed it to a cold, contracted while on a spree, on election night. His expectoration was tough and of a yellow color, sometimes streaked with blood, especially in the mornings.

On physical examination I found his chest expansion to be normal, and ordinary percussion revealed nothing abnormal; but on percussing the lungs as a whole, I noticed a decided difference in the pitch between the two sides of the chest, the right side being higher in pitch than the left. On auscultation, a few moist râles were heard in the middle and lower lobes of the right lung. On examination of the throat I found the velum and pillars to be intensely red, the pharynx dry and shiny, and the papillæ on the back of the tongue red and enlarged. With the laryngoscope I noticed the same intense red color in the mucous membrane of the larynx; the epiglottis was normal; the aryepiglottic folds were swollen and red; an ulcer, which seemed rather superficial, was noticed on the right arytenoid cartilage, while the left one was the seat of most intense inflammation; the vocal cords were slightly reddened and seemed somewhat thickened. On inquiry, the patient admitted that he had had a primary sore three years before, and had since that time suffered from other secondary syphilitic affections, but supposed to have been entirely cured, as he had not suffered from any of them for a year. A careful examination of the other organs failed to reveal any syphilitic affection in them, and I had been induced to suspect syphilis in this case from the appearances of the throat only.

I put this patient on the same treatment as the other one, omitting the inunctions of oil, however, as there was no difficulty of deglutition, and the patient could take enough food internally to build him up. After having taken the iodide of potassium for about a week, he complained of so severe a coryza and of other symptoms of iodism that I found it necessary to substitute daily inunctions of ½ drachm unguentum hydrarg. into the skin of the arms. After this he improved very rapidly, and four weeks later all symptoms of lung as well as of throat affection had disappeared, and he was able to go to work again.

Through a careful study of the above reported cases, as well as of a number of others similar to them, which, from time to time, have come under my notice, I have arrived at certain conclusions in regard to this affection, conclusions which are shared with me by other observers, and especially by Schnitzler ("Die Lungensyphilis," by Dr. John Schnitzler, Vienna, 1880), who reports a number of cases of syphilitic phthisis. Thus I found that syphilis of the lung is far more frequent than is generally supposed; that it usually shows itself in the secondary and tertiary stage of the constitutional affection; that the symptoms, on the whole, are those of pulmonary phthisis, and that even at the post-mortem examination the two morbid processes are difficult to differentiate; that the diagnosis must rely upon the changes in the lung, the previous history of syphilitic infection, and the demonstration of syphilis in other organs, especially in the larynx, which can only be done by means of the laryngoscope; that the prognosis is, on the whole, favorable, and that if the nature of the disease is not recognized early and treated accordingly, it usually runs into phthisis and ends in death; and finally, that the treatment should be anti-syphilitic, energetic, and carefully watched, and that if any lesions exist in the fauces or larynx they should be healed up by local applications. Then often wonderful results are obtained.

Hospital Reports.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

CLINIC OF PROF S. D. GROSS.

Reported by Frank Woodbury, M.D.

Stricture of Œsophagus, of Syphilitic Origin.

Gentlemen—Our first case to-day is one of stricture of the œsophagus, in a man who was formerly a nurse in this hospital, which you remember as the one in which I succeeded in passing a small bougie into the stomach at our last meeting. There was a want of resistance after passing the contracted part of the tube, which was sufficient evidence that I had gone beyond the stricture. There was also, as you remember, a little blood upon the instrument when it was withdrawn. On the day following the operation he was seized with pain in the limbs; he ached all over. There was also want of appetite, with increasing difficulty in deglutition. He required morphia for the relief of this pain, and we were obliged to support him by the method of rectal alimentation; milk and whisky, in the form of milk punch, with beef juice, were given, as enemata, several times daily. He feels very wretched, and is much opposed to this mode of nutrition, but we are obliged to resort to it, as he cannot swallow food in any form whatever.

The prognosis is poor. I merely brought him before you to show that he is worse than he was, and I will not, at present, pursue the treatment by dilatation. The stricture, from the history of the case, is probably syphilitic in its character, but whether it be so, or epitheliomatous, cannot positively be determined without a post-mortem examination; and the poor fellow has left directions that such an examination shall be made.

Stricture of the Rectum; Probably Syphilitic.

This patient (a woman, 27 years of age,) came here yesterday, from Washington City, on account of some trouble in the rectum. She brought a note, addressed to me, from Dr. Marker, Surgeon in Charge of the Columbia Hospital. In this letter the doctor says that Mrs. X. "has been suffering for several years with rectitis and stricture, supposed to be specific. She has used various rectal applications, iodoform, and had the stricture dilated with bougies, etc., though with but little benefit."

The first thing to be done is to make an investigation into the local condition. We may make an examination here with the finger alone, or the finger aided with a speculum. In most cases of stricture of the rectum the seat of the disease is found low down, or just within the verge of the anus; more especially so when it is of a syphilitic character.

Stricture in this situation may be caused by the discharge from a soft chancre or chancroid, or from a syphilitic chancre; the matter, passing from the vagina and vulva along the perineum, coming in contact with the parts, attacks the mucous membrane at the anus, as well as the tube within. In this way you will find rectal stricture not unfrequently caused in the female sex; but it also may be caused indirectly through a constitutional taint; the specific poison acting upon the system at large and making its local impression in this spot. Whether it is one or the other, in this instance, I cannot say; nor could I positively tell you, even after a careful examination, whether it is due to a syphilitic taint of the system, or to epitheliomatous disease of the bowel.

Epithelial cancer may occur in this situation, as it does in many other parts of the body, without obvious cause. It may appear at the anus and extend into the rectum, or may attack the bowel alone. In the latter case the disease is usually situated about two and a half inches above the anus, within easy reach of the finger.

Oiling my right index finger, and introducing it gently into the anus with a spiral motion, it comes in contact at once with a stricture about two inches above the sphincter. I am now passing through it, the surface of the stricture being around my finger; it is somewhat rough, and the opening is just about large enough to admit the index finger; it seems to be annular or circular in its shape. That is to say, it embraces the entire circumference of the bowel, having a central opening just sufficient to admit the finger. It is a thin stricture, not having much depth to it, about half an inch, apparently. I imagine that I could dilate this with my finger, but I will not do so without further deliberation.

When I say that I would not proceed without full deliberation, I mean to teach you that it would not be safe to dilate this stricture without proper care. Remember that this spot is the seat of purulent discharge, and has, therefore, chronic disease of its vessels; a rupture of this stricture might produce inflammation, which, extending to the peritoneum, would cause fatal inflammation. For this reason you should be very careful how you proceed in these cases. It would be better to wait, and after deciding to operate, incise this diseased mucous membrane by superficial longitudinal incisions, in several places, with the bistoury, before introducing a bougie. An ordinary spermaceti candle makes an excellent dilator; it is a capital bougie. The bleeding from these slight incisions or scarifications is usually insignificant, and can be readily stopped by applications of a piece of lint wet with Monsel's solution diluted with water.

The duck-bill uterine speculum, as it is called, of Sims, offers the best means of examination for rectal exploration; it is worth all the rest put together. Of course, before the examination is made, the proper plan is to empty the bowel with a large warm-water injection.

I wish to impress this point particularly upon your minds, that there is danger in meddling with a stricture without full deliberation and proper preparation of the case; for untimely or improper interference may result in fatal consequences.

The patient reports that her general health and appetite are good, and she considers herself, in all other respects, as in excellent condition.

Now if this disease be due to a taint of the system, as is supposed by Dr. Marker, the proper treatment would be to place her upon iodide of potassium with some salt of mercury—

℞. Potassii iodidi, gr. x
Hydrarg. chlor. corrosiv., gr. $\frac{1}{10}$. pro dosa.
Given in some proper menstruum.

The iodide is to be gradually increased to twenty-five grains given three times a day, if the stomach will bear it.

I am quite sure that even this would not be sufficient to cure the stricture unaided; it would only serve to relieve it to some extent, even with the assistance of the bougie. When the disease reaches this stage, entire relief is out of our power, but it may be held within bounds for a number of years, by attention to the general health and keeping the bowels loose, so that there are several passages a day. If the appetite continues fair, and the general health remain good, life may be prolonged for a number of years beyond what would otherwise be expected in these cases.

Paralysis of Forearm Following Injury Involving the Median Nerve.

This young man, twenty years of age, presents himself with some trouble in his left hand. You observe that he has lost power in the thumb and first two fingers, and that they are contracted and somewhat atrophied. He says that eight months ago he received an incised wound with an axe, just below the bend of the elbow, directly in front, where we find a decided cicatrix.

The injury doubtless involved the nervous supply of the thumb and adjoining fingers; the median nerve was probably divided; the ulnar nerve, supplying the little and ring fingers, escaped injury. The hand is cold; the circulation and innervation are both impaired. The wrist can be flexed, but there is some contraction interfering with full extension. He says his forearm feels numb. Comparing his upper extremities, we notice a striking difference between them; the muscles on the right side are developed to a normal degree; the temperature is good; here, in the left side, the muscles are flabby and soft, in consequence of want of due supply of nerve force and deficient amount of blood. The nerve current cannot pass to these muscles, on account of the injury to the main trunk, thus giving rise to fatty degeneration, absorption, and atrophy.

The question of treatment resolves itself into what shall be done to stimulate the nerve and give more blood to the part affected? I take it for granted that no treatment can restore the limb to a natural condition; the nerve has been divided and by this time has degenerated, so that the nervous fluid has been cut off from the outer aspect of the forearm, and also to the parts immediately below the line of the wound. Still, something can be done with a view of re-animating these structures. What I have the most confidence in is the hot and cold douche, daily applied, in some cases several times a day; pouring upon the limb in the first instance, from a little elevation (ten or twelve inches), water as hot as can be borne by the patient, followed by a similar amount of cold water, from a pitcher, flowing in a steady, continuous stream. Having repeated this, he shall take a fringed towel wrung out of cold water and slap the limb from the shoulder down to the hand, until the skin becomes thoroughly red. This is a powerful stimulant to the peripheral nerves and the capillary circulation. Indeed, I know of nothing, for such cases, as good as this. We may also use in combination veratria ointment—

℞. Veratriæ, ʒj
Unguenti, ʒvij. M.

Apply with the bare fingers, twice in twenty-four hours, a piece the size of a pea, which should be well rubbed in over the affected muscles.

I place great reliance upon flagellation with a towel, the fringe of which should be at least three and a half inches in length. It is a powerful excitant of reflex action. If I should ever be so unfortunate as to nearly lose a patient under the administration of chloroform, or any other anæsthetic, I should at once turn him upside down so as to make the blood run to the brain, and have him at the same time vigorously slapped with a fringed towel wrung out of cold water, in the manner just described; it is a powerful stimulant to respiration. If you have an asphyxiated child, from the effects of giving chloroform or ether during parturition, the best plan is to spank the infant well with a towel, in this way. Nothing can compare with it for effectiveness, it is better than the galvanic battery.

Paronychia, with Remarks upon Diagnosis and Treatment.

This young lady has a felon on the left index finger, involving the distal phalanx. Notice the swelling and discoloration around the nail, and at one point some appearance of pus. This is what we call a felon, paronychia, or whitlow.

This affection is exceedingly painful, especially so when deep-seated and when it involves the periosteum. In some cases the inflammation begins in the deeper layer of the skin, and may be comparatively superficial; but in others it commences in the periosteum, and involves all the structures in its progress from the bone to the skin. It frequently arises without any assignable cause; in some it follows slight injuries, such as the prick of a needle; and in other cases it is associated with some disorder of the general system.

The symptoms are familiar to you, from seeing similar cases previously; I need not dwell upon them. The proper treatment is free incision, making the knife grate upon the bone. This will reduce the tension, stop the burrowing of the pus, and yield infinite relief; it will also save the bone from destruction, if made sufficiently early. I laid great stress, the other day, when speaking to you on this subject, upon the importance of laying open a felon down to the bone; otherwise you will not have done your duty, and the bone may suffer necrosis.

Having now laid this freely open, I will order her an elm-bark poultice, containing some lead-water, and give quinine internally. I need not discuss the many new remedies that might be used with more or less advantage; it is not well to experiment with new remedies until we know exactly how much can be done with the old. Out of the vast number of preparations of the pharmacopœia, some fifteen or twenty will answer for almost every purpose for which the phy-

sician needs them; the others are relatively of little use. After all, the old friends are always the best.

Dislocation of Finger from a Fall—Reduction.

This man, sixty years of age, fell on going up his cellar stairs, and injured his hand. Notice the difference in the length of the fingers. In looking at the hand in profile, the middle finger looks as if the posterior portion of the second phalanx were thrown up on the dorsal surface of the first phalanx. We will give him a little ether, and reduce the dislocation.

Luxations are very uncommon, both of the phalanges of the fingers and of the toes; but still these dislocations may and do take place. When they occur they may be in two principal directions: upward, in which the distal may rest upon the dorsal surface of the first phalanx; and downward, or the opposite condition. Generally, the dislocation is upward and backward.

Anæsthetics make cowards of us all. No matter how innocuous the agent, there is always some apprehension on the part of the patient that he may not wake up; although the greatest care may be taken, still he will feel that accidents have happened, and they may happen again. We need, therefore, to reassure the patient, and not to refuse him our sympathy.

I have here a pair of forceps, made for this purpose, with which I seize the dislocated phalanx (the instrument being well guarded by a bandage), the assistant making counter-extension by grasping the wrist at the same time that I draw upon the phalanx and extend it, and it slips easily into place. We will now wrap up the joint in lead-water and laudanum. Passive motion should be instituted at the end of six or seven days, to prevent anchylosis.

Neurosis of Portion of Temporal Bone, Following Scarlet Fever.

E. C., six years of age. About the beginning of January, 1880, this little girl had scarlet fever, which was quite a severe attack, and was followed by continued depression. In the fourth week she had a large swelling behind the left ear, which opened twice, and has never healed. Last week a spicule of bone was discharged from behind the ear. There had also been a discharge from the ear, her mother says, during the progress of the fever.

Giving ether, I find a piece of dead bone presenting in the sinus, which is apparently a portion of the mastoid process of the temporal bone. This removed with the forceps, the surface of the sinus is scraped so as to put the ulcer in a proper condition for the development of healthy granulations, by which the wound will be healed. The further treatment of the case should be conducted upon general principles.

Hydrocephalus — Remarks upon Pathology and Treatment.

This baby, nine months old, shows a remarkable development of its head, it is, moreover, a very large child for its age. The sutures are quite widely open. The mother tells us that the child is fretful and seems sometimes to suffer pain. It has not had any convulsions. The circumference of the child's head is twenty four inches, two months ago it was twenty-two inches. Notice that the eyes are apparently small in proportion to the size of the head, and that they are in constant motion. This is due to pressure of the fluid contents within the skull upon the optic nerves. The eyes are somewhat inverted, there is a slight convergent squint. The child nurses well, can move all its limbs, urinates freely, and has no trouble with its bowels.

This is a case simply of ordinary hydrocephalus, although it was not noticed until the baby was about two months old. Beyond all question it was congenital, as is almost invariably the case in this disease. The amount of water present is evidently considerable, but, of course, its exact quantity cannot be estimated.

This affection corresponds in its pathology with hydrorachitis or spina bifida – hydrocele of the spine as it might be called —a collection of water in the membranes of the cord protruding through a congenital deficiency in one of the vertebral spinous processes.

The cause of this collection of water must be either some constant irritation of the arachnoid membrane; or, what is more likely, a want of balance between the secernent and absorbent powers. You know that there is normally a certain amount of cephalorachidian fluid. This was brought to the notice of the profession by an account published by Magendie in 1827, and had never been accurately described before. It is this fluid, existing in superabundance, which gives rise to this increased size of the skull, the bones are forced apart, as the sutures, the fontanelles are widely open.

The physical qualities of the fluid are the same as of the cephalorachid an secretion in its normal state. It is saline, contains just the smallest quantity of albumen, not coagulable by heat, nitric acid or the electric battery. If there was as much albumen here as in the fluid contained in a hydrocele, it might prove disastrous to the brain, and nature has, therefore, wisely kept the albumen away from these important structures.

What is to be done for the relief of this condition? Very little. When the disease has reached such a state as it has in the case before you, nothing remains but the hope for amelioration. The late Dr. Conquest, of England, published a series of cases, in all about fifteen or eighteen, where a cure followed the operation of tapping. I have not the slightest confidence in his statements, for the experience of the entire medical and surgical profession is against his conclusions. If he attained such success in so many cases, it is strange that the same thing could not be done in the practice of other physicians and surgeons. I, therefore, assume that there was no truth in the statement. The late Dr. Brainerd, of Chicago, also published a series of cases, embracing six or eight, in which the best results apparently followed the injection of iodine and iodide of potassium. Drawing off a certain amount of the fluid and injecting a small quantity of a diluted solution, containing iodine and iodide of potassium, was the method advocated by this surgeon, the operation to be repeated every six or eight days, and always preceded by drawing off a small quantity of the fluid. I cannot see upon

what this method depends for its good results, which, in truth, lack confirmation, for they have not been obtained by the other observers who have adopted this plan. I think that he must have been mistaken, although a man of great respectability and unquestioned veracity; yet mistakes will sometimes occur.

Another series of cases has been published by some one whose name I do not at present remember, but his method was based on the internal administration of iodine and the iodide of potassium, something on the plan of Dr. Brainerd. It has been, however, pronounced equally unsuccessful, by subsequent experience. The treatment is no more promising than that for spina bifida. Due attention to hygiene, and little, if any, medicine, is what I shall advise for our patient.

Diagnosis and Treatment of Tertiary Syphilis.

Wm. S., 38 years of age, when he was about 17 years old, had three chancres, followed by bubo in the right groin. Subsequently he has had mucous patches upon his lips, but no other manifestations of syphilis, for about thirteen years, until lately. He comes to us now, complaining of nocturnal pains, existing for the last week, in the shafts of the long bones. He also exhibits an indolent, ecthymatous, copper-colored eruption upon the dorsum of the left foot. On his back I also find a few rupial sores. These manifestations are characteristic of syphilis, and are evidently tertiary in their character.

There is no mistaking this disorder, even if the case were presented without a history. When you see such sores, covered with a blackish crust—rupial sores—there is no doubt whatever about the case; but when you couple with it the history of chancres, the evidence is conclusive.

For the relief of the nocturnal pains, and to heal up these sores, we will give him iodide of potassium and bichloride of mercury. We may scotch the syphilitic poison with the iodide of potassium, but if you wish to kill your snake you must also use a certain amount of mercury. I prefer the bichloride as being the most harmless and less likely to damage the patient's constitution. Other mercurial preparations are preferred by some surgeons, calomel, the biniodide, and the green iodide have each their advocates. Blue pill, mercury with chalk, and other preparations are also in use, but I have not the same reliance in them as in corrosive sublimate.

℞. Potassii iodidi, gr. x
Hydrarg. chlor. corrosiv., gr. ⅛
Infusi gentianæ comp., fl. ℥ ss. M.
For a dose, three times daily.

As the medicine is apt to disagree with the empty stomach, it is best to give it after each meal. If it nauseates, let the quantity be reduced.

Under the influence of these two remedies the nocturnal pains may be relieved in the course of a few days. We should have warm baths (about 85°) every few days, in which might be placed some bran and salt. Let him remain in the bath for half an hour. Keep the skin moist and clean, and apply to the sores some benzoated oxide of zinc ointment, and Goulard's cerate, of each equal parts. The sores on the foot seem more inflamed and should be wrapped up in some acetate of lead solution. His diet and clothing will also be looked after.

Result of Resection of Shoulder-Joint.

The case just shown is also one of surgical interest from another point of view. He has lost about three and a half inches of the upper extremity of his right humerus, from a gunshot wound of the shoulder received in the last war.

The operation of excision of the shoulder joint is often practiced. first, on account of pathological conditions of the humerus and scapula, and secondly, on account of external injury, especially gunshot wounds. The operation is easily done, by making, as I prefer, a perpendicular incision through the deltoid, beginning at the acromion process and passing downward, making a wound about four and a half to five inches in length, directly down to the bone. Then peel off as much of the periosteum as is thought necessary, and cut off its sharp edges with the pliers. The operation was performed in this way, for the perpendicular line of the cicatrix is plainly seen.

He has considerable power of movement in the newly formed joint. He can raise the arm in front to a right angle, although undoubtedly a considerable portion of the bone has been removed. As he has full use of the forearm and hand, you see it is very much better than no arm at all. The operation, he tells us, was performed sixteen years ago, at the close of the war.

Medical Societies.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Stated meeting held on Friday evening, March 25th, 1881, at the house of Dr. Isaac Barton. The president, Dr. J. Solis Cohen, in the chair.

Before the meeting was formally opened Dr. Cohen exhibited a patient with extensive ulceration of the epiglottis and larynx, and Dr. Barton showed a case of congenital syphilis in a young girl involving the nasal, pharyngeal and laryngeal cavities.

After the members had examined the cases the president called the meeting to order. Dr. Barton then read a very interesting paper on "Medicated Gelatine in the Treatment of Nasal Catarrh." (See p. 401, No. 1258.)

Dr. Allen said that in his opinion gelatine was the proper material for carrying remedies and keeping them in contact with the mucous membrane of the nose, and stated that he had found a number of persons greatly relieved from attacks of hay fever by the introduction into the nose of soft pieces of gelatine saturated with iodoform. The subject of nasal catarrh was then at length discussed by most of the members present.

Dr. Seiler then read a report of two cases of pulmonary syphilis which he had been able to diagnose from phthisis and had successfully treated with iodide of potassium and mercury. He stated in his paper that, according to his own experience and that of other observers, syphilitic phthisis was more common than generally sup-

posed, and that the differential diagnosis between this affection and ordinary pulmonary phthisis could only be made out with any degree of certainty by the demonstration of the presence of syphilitic changes in other organs beside the lungs, and especially with the laryngoscope in the larynx.

This paper, together with the cases shown before the meeting, was then discussed by most of the members present, and the question was raised whether the case exhibited by Dr. Cohen was one of syphilis or of tuberculosis of the larynx. The Doctor stated that there was no history of specific infection, or of any of the usual secondary affections, and there was an absence of the intense injection of the mucous membrane of the palate and fauces so characteristic of syphilis; that there was, on the other hand, a soft tumor the size of a shelled almond in the soft palate, a slight swelling of one of the glands in the left groin, and that the lower portion of the right lung only was implicated to a very slight extent, which, as Doctor Seiler had pointed out in the paper just read, was the usual seat of lung infiltration in syphilitic phthisis. No definite conclusion as to the nature of the case was reached. Doctor McCracken then exhibited several samples of throat lozenges which had been manufactured for him, from his own formulæ. After this the Society went into private session. C. Seiler, M.D., *Secretary.*

Editorial Department.

Periscope.

Treatment of Diphtheria.

Dr. Thomas Barling describes, in the *Michigan Medical News*, February, his treatment of diphtheria. He says:—

I attend to four things: 1. Hygiene; 2. General Health; 3. The Throat; 4. Counter-irritation.

1. I insist on great cleanliness of person and surroundings; a moist atmosphere, easily obtained by mopping the floor and keeping a milk pan of water on the stove, and a disinfectant produced by half filling an old milk pan with moist earth, placing it under the stove, and putting into the moist earth fifty or sixty matches (generating ozone) and thirty or forty drops of carbolic acid, renewed three or four times a day.

2. For general symptoms, such as high pulse, pain in back, dry skin, increased heat, general uneasiness, and glandular throat swellings, I give one dose of calomel, five to twenty or thirty grains, followed in about six hours by a dose of castor oil.

3. The throat. At the commencement there are swollen tonsils, greatly enlarged capillaries, quickly followed by the diphtheria effusion, always accompanied with an increase of temperature of from two to four or even five or six degrees. I combat this with cold. I give a solution of

℞.	Acid. tart.,	gr. iij
	Pot. chlor.,	gr. iij
	Water,	℥ ij. M.

Order one teaspoonful to be mixed with two teaspoonfuls of the coldest water they can get; if ice water, so much the better; if no ice is to be had, cold well water, readily to be obtained, at about 45° or 56°; two teaspoonfuls are to be used as a gargle and the remainder swallowed. This to be repeated every twenty or thirty minutes, till the urgent symptoms subside. Little four year olds will eagerly look out for the gargle and long for the time for its repetition. I use no spray, no tannin, no swabbing, but I expect the urgent symptoms to be relieved in about twenty-four hours. I then generally give a gargle composed of

℞.	Red pepper,	10 grs.
	Common salt,	30 grs.
	Water,	½ teacup.

To be used freely, and if the tonsils remain enlarged and flabby, finish off with two or three applications of a strong solution of nitrate of silver, three or four grains to the drachm, applied with a feather.

4. Counter-irritation. There is well nigh always severe glandular swelling of the throat externally. I attack this by local sweating. I procure generally a handkerchief, fold it so that it will lay well into the throat, wet the handkerchief in hot water, so hot as almost to scald, and sprinkle it with a teaspoonful or two of kerosene, place this quickly on the throat, and cover with a dry cloth. This may want renewing three or four times at intervals of six or eight hours. This will blister severely; when this effect is produced still continue the wet compress, but put a little sweet cream on the wet cloth instead of kerosene.

This mode of treatment with me cures diphtheria. My total deaths did not amount to five per cent.

The Viburnum Prunifolium in Uterine Diseases.

Dr. E. C. Mann writes to the Boston *Medical and Surgical Journal*, February 24:—

As many cases of diseases of women occurring in connection with nervous diseases are annually treated here, I desire to call attention to my own investigations with this comparatively new medicine. It appears to me to act directly and specifically upon the special nerves of the uterus as a true nerve sedative. I have had several very violent cases of congestive and neuralgic forms of dysmenorrhœa, in one case the dysmenorrhœa being accompanied by epileptiform convulsions of a very severe type, and in each and every case I have seen almost magical relief following the use of the fluid extract of viburnum prunifolium. The case referred to, which was so severe that the intensity of the pain had worn out the unhappy sufferer and induced the epileptiform at

tacks, was completely cured in a few weeks by the combined use of the viburnum prunifolium and the use of the constant current of electricity, the positive pole being applied to the hypogastric region, and the negative pole, to which was attached a cup shaped electrode, directly to the uterus. The galvanic current has a very powerful influence in suspending contractions of the uterus, and also is very efficacious, when used locally over the ovaries, in controlling ovarian neuralgia. Previous to my using viburnum prunifolium I had been accustomed to rely on valerianate of zinc and fluid extract of gelsemium, with the constant current of electricity, but since my first experience with the former drug I have used nothing else. Although I have not had occasion to use it in cases of threatened abortion, I should deem it worthy of use from its action on the ganglionic nerve of the uterus. I have failed to perceive any action on the general system, the whole force of the medicine appearing to be directed to the uterus and its system of nerves. When the pulse has been high, from nervous excitement, and the temperature centres in the brain have been temporarily paralyzed, allowing sudden rise in temperature, from nervous excitement, both pulse and temperature have fallen to the normal as the uterine pain has been relieved. It must be remembered, also, that my cases have been aggravated ones, many of my cases having been sent to Sunnyside on the verge of insanity. My conclusions, therefore, are, that in viburnum prunifolium we have a uterine sedative more powerful than any other in controlling dysmenorrhœa and uterine contractions, and that it probably acts by passing from the blood to the nerve centres, and is special in its effect upon the ganglionic nerves of the uterus.

Earache and Its Treatment.

The following is from an article in the *Canada Lancet*, by G. S. Ryerson, M.D., L.R.C.P.S.E., Toronto, Lecturer on the Eye, Ear and Throat, in Trinity Medical College, Toronto:—

Pain in the ear may depend upon inflammation of the external auditory canal, the middle ear, or upon neuralgia. Inflammation of the external auditory canal may be diffused or circumscribed. When diffused, the auditory canal is greatly swollen and may be completely closed. It is hot, dry, and covered with dry flakes of epithelium. It is pale red in color and has a puffy or œdematous look. Pain is considerable, but the patient is as much distressed as suffering. Moving the auricle, or touching the part causes increase of pain. The hearing is dull and there is much tinnitus, roaring and throbbing.

The causes are exposure to draughts; irritation of a foreign body, as a plug of wax, and imperfect drying of the ear after bathing. A chronic form may be induced by the bad habit of picking the ear with pins.

The treatment is simple; it consists, in the early stage, of inflating the middle ear with Politzer's air bag, thus opening up the Eustachian tube and permitting the accumulated fluids to escape. Filling the ear with warm water will often give relief. Eight to ten drops of atropia sulph. grs. iv, aq. ℥j, should be instilled in the ear every two hours. A leech applied to the tragus will give great ease. The wound should be encouraged to bleed for some hours after the leech has fallen off. Should the patient be seen later, when there is much bulging of the drum-head, paracentesis should be done, with good illumination by a head mirror. This at once relieves the intense pain, saves the drum from loss of substance, and the ossicles from displacement. It also heals up more readily than when ulcerated. Should the drum have burst before the practitioner is called in, acid boracic, grs. xv, ad aq., ℥j, and zinc. sulph., grs. v, ad aq. ℥j, will be found to gradually arrest the discharge. The ear should be frequently syringed and the greatest cleanliness observed. *Poultices should never be applied to the ear.* Laudanum and oil are of little use. It also frequently follows measles and scarlatina. Neuralgia of the ear is rarely met with, and then in nervous women. It does not differ essentially from neuralgia in other parts. There is sometimes abnormal sensibility to sound present, more often, however, deafness. The treatment is principally tonic. There is no special local treatment which can be relied upon.

The Diagnosis of the Forms of Insensibility.

In a lecture in the *Lancet*, Dr. Reginal Southey says:—

In every case of coma count the respiration, observe the quality of the breathing, and its ordinary effect upon the blood by the color of the lips. Examine the pulse carefully for quality, frequency, regularity. Touch the eyeballs, examine the pupils for reaction to light, their condition—dilated, contracted, unequal, irregular; tickle the soles of the feet, to test what amount of reflex muscular action can be coördinated. The breathing in most states of coma is heavy and slow; notice if it be stertorous, Cheyne-Stokes like, wholly diaphragmatic, or if the intercostals act. Next take temperature in the axilla or rectum. A remarkably low temperature, four degrees or more below normal, betokens usually uræmic coma, acetonæmia, or grave concussion of the brain. After epilepsy, apoplexy, intoxication, the temperature is more often normal, or even slightly above normal.

Uræmic coma will again be separately distinguished most often by some slight œdema of eyelids or extremities; waxlike pallor, bronchitic sounds, very foul breath, smelling of beef tea; a brown, furred tongue, pearly conjunctivæ, and dilated pupils bespeak urea poisoning. Diabetic coma is indicated by oppressed, noisy breathing, effected by abundant muscular effort, but attended by some lividity, in evidence of impaired oxidizing changes at the pulmonary capillaries, of which we do not at present understand the exact cause.

In the coma that has succeeded an epileptic fit you may expect to find bruises, torn or dirtied clothes, indications of the tongue having been bitten.

Finally, the mode of recovering consciousness after intoxication differs much from what is observed in persons recovering from the coma that

succeeds an epileptic fit. After intoxication I have noticed that while the sense of hearing is recovered soon, the lower attributes of mind, the sensorial instincts, reappear early; the individual who was comatosely drunk hears correctly before he sees correctly, and sometimes before he can stand. It is curious to notice the manner in which he repeats a word of your question over and over again, like a parrot, and perceive how some grotesque idea grows out of the jingle or jangle of a phrase mumbled over more or less thickly.

How differently do the mental faculties recover after brain concussion and commotion, as after epilepsy. How the intellectually reduced "egomet" is in a dreamy state and staggers in his gait, hears questions put to him correctly, answers them articulately, apparently rationally, but having done so straightway forgets what he has said, cannot tell where he is or what he is or was doing. He is conscious of some confusion in his own memory, and shows often some high measure of judgment in his distrust of himself, and says, "I cannot recollect where I was going."

It remains for me to point out the distinctive features of opium coma. There is profound stupor, with closed eyelids, contracted pupils, upturned eyeballs; the face is pale; the skin cool, clammy; the forehead beaded with heavy perspiration; the limbs are lax, but, for a while, reflex motions are readily excited. The respiration now slackens, falls in frequency, perhaps, as I have seen it do, to as low an ebb as six per minute, the pulse remaining fair at eighty. The coma now is very profound; you may prick, stimulate by galvanism, call, flick, stimulate by what means you please, little or no further purposive response is returned by coördinated muscular movements. The body will not walk; it is only dragged about, if the advice given has been to walk the man about. Next the lips get livid; the surface of the body colder; the breath is sobbing, and at long, irregular intervals; the pulse hardly to be felt at the wrist, and death is imminent by asthenia or sudden failure of the heart's action. Now for what may you mistake this coma, and what may be most easily confounded with it? Apoplexy into the pons Varolii, since, as was pointed out long since by Dr. Wilks, who illustrated the fact by several examples of cases that had fallen under his observation, apoplexy into the pons is attended by great contraction of the pupils.

The Effects of Varicocele on the Testicle.

Varicocele is so frequent that some observations made this past winter by Mr. P. Gould, and reported to the Clinical Society of London, will have general interest. Mr. Gould exhibited two men to the Society, each presenting a large left varicocele, with the testicle on the same side much smaller than its fellow, but retaining its usual firmness, outline, and testicular sense. The one man, aged 18, had noticed the swelling in the scrotum accidentally, four or five months ago. The other, aged 17, had noticed the varix for six or seven years. In neither case was there any pain or disturbance to be traced to the varicocele. Neither patient had suffered from inflammation of the testicle or any injury to the scrotum. They were both well made, robust, healthy-looking men. Mr. Gould quoted the views of Sir James Paget and Mr. Curling, as illustrating the opposing doctrines on the question whether varicocele did or did not cause wasting of the testicle. After enumerating a list of authors who supported Curling in his opinion that atrophy of the testicle did result from varicocele, he observed that many of the cases cited in support of this assertion must be excluded, on account of the traumatic origin of the varicocele; wherever there was a history of injury or inflammation, it was impossible to say that the change in the testicle was not the direct result of such injury or inflammation. Again, cases where there was no mention made of the presence or absence of these conditions were also of doubtful value. With these reservations, the alleged cases of atrophy were of three kinds: first, cases of arrested development of the testicle, illustrated by the cases shown; second, cases of very slight lessening of the size of the testicle, said by many authors to be very common; a condition of which it was difficult to be certain. Mr. Gould had never seen the left testicle larger than the right—its normal relation—when there was a large varicocele on the same side. Thirdly, there were cases of morbid and extreme softening and wasting. Although cases of this kind were recorded by Curling, Richter, Landouzy, and others, no mention had been made of the absence of previous injury or inflammation of the testicle; and they were not entirely free from doubt on that account. There was strong reason to think that varicocele might produce such wasting of the gland. Referring to the frequency of varicocele on the left side, Mr. Gould argued that neither the greater length of the spermatic vein on that side, nor its lying beneath the sigmoid flexure, nor the mode of entrance into the left renal vein, was sufficient explanation. It was maintained that the use of the valve at the mouth of the spermatic vein was to convert the direct opening into an oblique aperture, and, by lessening its size, cause the flow of blood over it to exert an aspirating effect. Many differences between varicocele and other external varices were pointed out; and the opinion was advanced, that many cases of varicocele were nævoid in character—a primary abnormal development of the veins.

Gelsemium in Incipient Epilepsy.

Drs. A. W. Wiseman and W. L. Crump say, in the *Virginia Medical Monthly*, February, 1881:—

We attended together a case of cerebro-spinal meningitis in a young married woman, nursing her third child, which was a few months old. The patient's parents on both sides were strumous. The case was complicated by slight typhoid symptoms. After convalescence from the meningitis was fairly established, she commenced having epileptic fits. We tried chloral, morphia and bromide of potassium, the last.

named remedy being pushed to the degree of causing nausea, yet without any beneficial effect. We saw that unless something more was done we would have a case of confirmed epilepsy to deal with; we put her upon the fluid extract of gelsemium, three drops every two hours, and gradually increased the dose to nine drops. Amendment was noticed in two days, and in one week the fits ceased. Several months have elapsed, with no return of the disease.

In a case of hystero-epilepsy, in an unmarried colored girl of about twenty (menstruation normal), with intense clavus hystericus and hemianæsthesia, which had been a very troublesome case at different times, we pushed the gelsemium until fifty-eight drops were taken every two hours, for days together, with the effect of quelling the paroxysms. A few mild attacks came on afterwards, but were controlled by the medicine, and they gradually subsided, and for several months there has been no return.

The range of the dose is considerable, for during the same time that we were treating the last-mentioned case, one of us treated a rather sthenic case of pneumonia in a young married woman, nursing her third child, which was a few months old, and four drops produced the peculiar constitutional effects of the drug. The patient rested as quietly as if she had been asleep, and afterwards said that she could hear the attendants discussing whether she was asleep, and sometimes she could hear some of them say "Now I know she's asleep." And yet the pulse was only reduced from 120° to 112°.

The Diagnosis of Jaundice.

The following useful epitome is taken from Dr. J. W. Legg's late work on Bilious Diseases. It gives his directions regarding the diagnosis of jaundice:—

1. Should the jaundice be recent, and no perceptible disease be found in the liver or elsewhere, the case is probably one of simple jaundice.

2. The jaundice being recent, but acute disease of other parts present, such as pneumonia, pyæmia, typhoid and relapsing fevers, and the like; delirium tremens, poisoning by chloroform, chloral hydrate, and other drugs, and snake-bites, the cause of jaundice is not known with any certainty; but it is probably the same as in simple jaundice.

3. If the jaundice be accompanied or preceded by attacks of severe shooting pains in the right hypochondrium; or if the jaundice be intermittent, one attack quickly succeeding the other, the cause is probably gall-stones.

4. An intense, persistent jaundice, if approaching twelve months in duration, is due, probably, not to cancer, but to gall-stones, hydatids, or stricture of the duct.

5. A slight, persistent jaundice is probably due to changes in the texture of the liver, as cirrhosis, nutmeg liver, etc.

6. Jaundice with great enlargement of the liver is probably due to cancer.

7. Jaundice complicated with ascites is probably due to cirrhosis.

8. Delirium setting in during an acute jaundice suggests *icterus gravis*.

Reviews and Book Notices

NOTES ON CURRENT MEDICAL LITERATURE.

——A very neatly gotten up and curious addition to medical literature, is a series of phototypes of bogus diplomas, bought for $455.00, in May, 1880, by a representative of the Philadelphia *Record*, "who had no knowledge of medicine and had never seen the inside of a Medical College." It contains phototypes of a diploma of the "Eclectic College of Pennsylvania," of a certificate of membership of the "National Eclectic Medical Association," a diploma of Doctor of Laws, of the "American University of Philadelphia," one of "Doctor of Divinity," of the same institution, one from the "Livingstone University of America," and one from the "Philadelphia Electropathic Institution," conferring the degree of "Master of Electro-Therapeutics" (Drs. Galloway and Bolles' concern). All these were bought outright, by a person wholly ignorant of medical science.

——The address delivered before the graduating class of the Medical Department of the State University of Iowa, by Dr. S. B. Chase, has been published in neat form, by the class. The subject is "Our Life Work," and it is well treated.

——Various papers contributed to the Boston *Medical and Surgical Journal*, by Dr. Thos. H. Buckler, of Baltimore, have been collected and published by Houghton, Mifflin & Co., Boston (paper, pp. 72).

The topics are "Strangulated Veins of the Uterus," "Post-parturient Pathology," "Free Access to the Abdominal Cavity," etc.

——Dr. Rosalino Rovira y Oliver, of Barcelona, has sent us his thesis on pneumoconiosis, or the effects of the inhalation of dust. He dissents strongly from various French authorities, who have spoken of the effects of dust in the lungs as trivial. On the contrary, the inhalation of dust consisting of sharp spiculæ leads to a dangerous irritation of the lung substance, the patient often dying with one of the forms of phthisis. He draws a broad distinction between the effect of such dust and that which is composed of soft particles. The whole thesis is carefully prepared, and indicates original study of the subject.

——A series of statistics of the weight and size of the body and its organs has been prepared for the use of medical students, by Dr. J. S. Wight, Professor of Surgery at L. I. College Hospital, and published by Trendett & Co., Brooklyn. It makes a neat pamphlet of twenty-six pages, and is useful for reference.

——The annual report of the German Hospital for this city indicates the institution in a flourishing condition.

BOOK NOTICES.

The Metric System in Medicine. Containing an account of the Metric System of Weights and Measures, Americanized and simplified, a Comprehensive Dose Table, and practical illustrations of Metric Prescriptions. By Oscar Oldberg, PHAR. D., etc. Philadelphia: Presley Blakiston, 1881. Cloth, 8vo. pp. 182. Price $1.50.

The contents of this volume are quite fully set forth in the comprehensive title which we have above quoted. It is addressed both to pharmacists and physicians who wish to familiarize themselves with the metric system as it is recommended by its advocates for introduction into this country—"Americanized," as Dr. Oldberg calls it. The arrangement and contents of the work are well adapted for this purpose. A historical sketch of its earliest introduction into the United States is given, and a number of rules for the ready conversion of the usual apothecary's into metric weights and measures are advanced. The posological table is very complete, and the metric formulary will be welcomed by any who wish to familiarize themselves with accurate metric prescriptions. Of the several adaptations of the metric measures to the supposed wants or wishes of the American medical public, this is no doubt the most approved and the only official one, inasmuch as it has already been adopted by the U. S. Marine Hospital Service, in which the author is Medical Purveyor.

A Manual on Diseases of the Eye and Ear. For the use of Students and Practitioners. By W. F. Mittendorf, M.D., Surgeon to the New York Eye and Ear Infirmary, etc. Illustrated. G. P. Putnam's Sons. 1881. Cloth, 8vo, pp. 445.

The author of this work has designed it to be a short and practical manual of the diseases of the organs of which it treats, designed primarily for students and those practitioners who have time to make but a cursory study of these special branches. He has succeeded in presenting a large number of these maladies, all, in fact, which are usually met with, writing as fully as possible on their description, treatment and differential diagnosis. His arrangement is the simple anatomical one. Beginning with the orbit, he speaks of the lids, lachrymal apparatus, muscles of the eyeballs, the conjunctiva, cornea, etc. There are a moderate number of wood cuts and ten full-page plates, colored lithographs, taken from the works of Sichel, Liebreich, and Wells. These plates, though at first glance an attractive feature of the book, are, with two exceptions, of little practical value, and they are not executed with any great amount of skill. Nor can we say much in praise of the wood-cuts; they are rough and too few to be of any real use to the reader.

Four chapters, in all about a hundred pages, are devoted to the diseases of the ear. The directions for using the ophthalmoscope and otoscope are somewhat scanty, and, especially the former, might have been bettered by the more free use of illustrations, and a much more detailed description of the procedures neccessary.

A Guide to the Clinical Examination of Patients and the Diagnosis of Disease. By Richard Hagen, M.D. Translated from the Second Revised and Enlarged Edition, by G. E. Gramm, M.D. Bœricke & Tafel, Philadelphia. 1 vol., cloth, pp. 223.

We have known and appreciated Hagen's work for a long time. It has met with considerable success in Germany, and has held its own as a student's guide to diagnosis for a number of years. But why did the present translator take the *second* edition, published as far back as 1873, for his translation, when a *third*, with important additions, appeared in 1877, and perhaps yet another later than that? Such neglect to obtain the latest improvements of the author is censurable.

The volume begins with some introductory remarks on symptoms and general definitions. The reader is then instructed in the general clinical examination of the patient, his previous history and his *status præsens*.

The rules for special clinical examinations are divided into those for patients presenting symptoms pointing to a disease of the lungs, the heart, the abdominal organs, the brain, the skin, the spinal cord, poisoning, etc. The directions given are clear and concise, and the book is a valuable addition to the literature of diagnosis.

It is neatly printed, with a full alphabetical index, and the translation is fairly well made.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE CONSUMPTION OF OPIUM IN THE UNITED STATES.

The enormous consumption of opium in the United States is naturally attracting the attention of those familiar with our commercial statistics. Of the entire crop of Turkish or Smyrna opium we use considerably more than half. The whole of Europe takes only about three-eighths of it. The actual weight in pounds is 372,000. About a quarter of this is used in the manufacture of morphia, of which we may suppose 80,000 or 100,000 ounces are made and consumed inside our borders.

There has also been recorded a steady and rapid increase in the demand for opium in the United States; an increase much out of proportion to that of our population. This is evident from the following table of imports in different years:—

In 1859,	71,839 lbs.
1860,	135,000
1867,	135.305
1876,	228,742
1877,	230,102
1878,	207,752
1879,	278,554
1880,	372,000

Here is an increase of four or five hundred per cent. in twenty years.

These estimates were furnished the *American Journal of Pharmacy* last December, by Mr. R. F. FAIRTHORNE, of this city. He adds:—

"Why so much larger quantity is consumed in this country than in Europe it would be difficult to determine. The greater number of persons suffering here with neuralgic troubles cannot possibly account for it. It is time that every physician and druggist should use his utmost efforts to restrain the improper use of opium. Undeserving, indeed, is he of the name of good citizen who carelessly dispenses these or other pernicious drugs for the sake of paltry gain."

Such a warning is indeed timely. It is impossible to resist the conviction that the "opium habit" is silently and secretly extending itself among our population. We believe that it prevails more widely than is generally credited. Very many persons indulge for years in small quantities of opium daily, merely as a stimulant.

It is a mistake to suppose that opium-eating, or the abuse of the drug in any of its forms, certainly leads to great excess in it. On the

contrary, most opium consumers are not opium debauchees, any more than most of those who use alcoholic beverages become drunkards. Whatever temperance orators like to say, such is not the case. By far the majority of moderate drinkers continue moderate to the end of their lives. They do not become sots, and feel no temptation that way; but they like their tipple for all that. So it is with opium. The most reliable English medical observers in the East agree that the "frightful examples" of opium victims are rare, and the habit is by no means so generally destructive as some have made it out to be, and as the popular impression is—an impression, we must say, encouraged in the popular mind by some enthusiastic physicians, who should know better. Thus, in a recent number of the *Popular Science Monthly*, Dr. Felix L. Oswald expresses himself in this style on the subject:—

Your body becomes an opium machine, a physiological engine moved by poison, and performing its vital functions only under the spur of the unnatural stimulus. But by and by the jaded system fails to respond to the spur, your strength gives way, and, alarmed at the symptoms of rapid *deliquium*, you resolve to remedy the evil by removing the cause. You try to renounce stimulation, and rely once more on the unaided strength of the *vis vitæ*. But that strength is almost exhausted. The oil that should have fed the flame of life has been wasted on a health-consuming fire. Before you can regain strength and happiness your system must *readapt* itself to the normal condition, and the difficulty of that rearrangement will be proportioned to the degree of the present disarrangement; the further you have strayed from nature the longer it will take you to retrace your steps.

This is set forth as the usual result of small indulgence. It is a greatly-overdrawn statement, and we gravely doubt about the propriety of presenting this as the result of science; or rather, we have no doubt at all on the subject, firmly believing that all species of misrepresentation should be avoided, as ultimately hurtful to a good cause.

On the other hand, no one should underestimate the injury which opium does work on many minds and bodies. It is so great and so enduring that active repressive measures of the opium trade should be taken in every State. No form of the drug should be sold except by a physician's prescription. It should be classed with poisons, and thus be placed out of the reach of the public. The patent medicines which contain it should be prohibited, and general information as to the dangers run by those who consume it should be disseminated.

There is no question but that the better class of pharmacists would assent to such measures, and would actively aid in having them carried out.

THE RELATIONS OF HYBRID MARRIAGES TO SEX IN OFFSPRING AND FECUNDITY.

The observations which we made in a recent number, on the rules for the decision of sex in the human species, explain some curious facts which have impressed students of statistics.

One of these is the preponderance of females among what may be called human hybrids—the children of marriages in which the father and mother belong to different races, as the black and white, or the red and white. This has lately been brought to the notice of the profession by Prof. Harvey L. Byrd, of Baltimore. In the October number of the *Independent Practitioner*, he says:—

"A curious and interesting fact in regard to the admixture of blood as it occurs in the human hybrid—mulatto—seems,so far as I have learned, to have escaped the notice of those who have written on the subject of the interbreeding of the Caucasian and Negro races."

The fact he alludes to is the one above mentioned, and his observation, though not so novel as he believes, has additional value as an independent corroboration of that of others.

The like has been noted of mixtures between the American Indians and whites. Thus, Mr. Stephen Powers writes: "A noteworthy phenomenon with regard to California half-breeds, which I have observed, and which has been corroborated by others, is that the girls generally predominate. I have often seen whole families of half-breed girls, but never one composed entirely of boys, and seldom one wherein they

were the more numerous" (*Tribes of California*, pp. 149, 403).

The explanation of such facts, according to the hypothesis of Dr. MORTIMER GRANVILLE, (see REPORTER, as above) would be that the prevalence of females indicated greater sex force on the part of the corresponding parent. In his opinion it would indicate a want of fulfillment of the full intention of nature. His views are thus stated in the *Lancet*, December 18th, 1880:—

1. Sex is the result of an arrest or repression of the force of development in the case of the female. The male of every family in the animal kingdom is the best and fullest specimen of development, having regard to the purposes and habits of life of the species, class, or family. In those apparent exceptions where the male is the smaller and less *displayed* animal, that is because it is an advantage in regard to the *life* and habits of the class to be small and unobtrusive.

2. The arrest in point of development which characterizes the female has nothing in common with immaturity, and is, therefore, not a conclusive proof of inferiority. It is, as it were, a *repression* of the formative force, and the physical result of this repression is a perpetual effort to develop or reproduce. The force arrested in the individual gathers intensity, so to say, and expresses itself in a perpetual and characteristic longing to produce a perfect animal. The perfection denied or inhibited in the individual is sought in the progeny. Hence the natural tendency of the female to produce male children, and, as a necessary result, the majority of children born are males. It is not a question of the comparative *amount* of ardency in the two sexes, but of the direction of the force or intention—I do not now mean conscious intention, but the intention or purpose of nature—in the case of the female. This direction will always be followed in sex determination unless that force is neutralized by the male.

3. The function of the male is not one of production, but of fecundation. The tendency of what I have called *ardency* in the performance of this function is to neutralize or control the productive force of the female, and thus determine that *arrest* of development which results in female offspring.

We are far from subscribing to the theory here proposed. On the contrary, many serious objections arise to it.

Mr. POWERS, in the work from which we have quoted, refers to the fact that in nearly all mixed marriages it is the male of the higher race who selects the female of the lower race; but, also, that the male is very apt to be a poor and degraded specimen of the higher race, while the female is nearly sure to be an unusually attractive and favorable specimen of the lower race. It is she who possesses the greatest amount of reproductive power; and possibly for this reason impresses her sex on her offspring.

The statement is made by PRITCHARD and others, that when women of the lower races—especially of the Malayan races of the Pacific islands—have once conceived by a white man, they do not at all, or they do with much less readiness, conceive by a male of their own race. This is one cause of the rapid disappearance of the native population from those islands.

If substantiated, this fact is contrary to what occurs in the lower animals, in whom it is so much more easy to conduct observations on this subject. A striking example was reported last year, in a veterinary journal published at Lyons, France. A mare, about ten years old, gave birth, at full time, to a foal. Soon after, the throes of parturition recommenced, and with assistance another foal was brought into the world. Twin foals are sufficiently rare to cause astonishment at any time, but the astonishment of the attendants was changed into amazement when they discovered that it was not a horse foal they had taken from the mare, but an unmistakable mule. The little creature, unfortunately, did not long survive its birth.

The veterinary surgeon who was subsequently called in made inquiry into the case, and as a result he gives the following explanation: It is a very common practice in Dauphiné to present the mare, when in œstrum, twice to the stallion, and at brief intervals, believing that fecundation is more certain by this procedure. But, as it seldom happens that the villagers can obtain the services of a stallion which can serve the mare twice, with only a few minutes between, or yet a second stallion, and as male asses are by no means scarce, they oftentimes employ one of the latter to succeed the horse. And this is what happened with the mare alluded to.

Such occurrences are rare, but we believe there are in the human race some few cases recorded where twins seemed to indicate that they owed their life to fathers of different races, the negro and the white, for example.

Notes and Comments.

Treatment of Skin Diseases.

Dr. H. S. Purdon, physician to the Belfast Hospital for Diseases of the Skin, gives a brief account of his treatment in the Dublin *Med. Jour.*, March. He says: "For acne I am using, with benefit, glycerine internally, as suggested originally by Gubler—a substance so analogous to oils, and, like them, following the ordinary modes of elimination, in traversing the sebaceous follicles; while locally, if on the face, my friend Dr. Samuel Moore's ointment of sulphur and green iodide of mercury is the most useful application I know of. Acne, in young men and girls, often attacks the shoulders. Here, sponging with sea water and brisk friction with a rough towel is far over ointments or lotions. For parasitic affections due to vegetable growths, croton oil liniment, by producing suppuration, destroys the growth more rapidly than any of the vaunted parasiticides. The solution of the ethylate of sodium I still use in nævi, small warty growths, and some forms of lupus, although Volkmann's spoon is the best means of quickly curing the patient. For lupus erythematosus the local application of liquor potassæ has given me good results, while internally, in the acute stage, large doses of acetate of potassium relieve the congestion, and in more chronic cases I prescribe Thompson's solution of phosphorus. In chronic psoriasis I think there is nothing to equal either cold or tepid 'packs,' as used at the hydropathic establishments."

Scrofula and Syphilis as Related to Typhoid Fever.

In an article in the Dublin *Medical Journal*, March, Dr. Henry Kennedy states that he has observed that typhoid fever occurs chiefly in persons of a strumous diathesis: he observes:—

"In typhoid cases I have seen, again, and again, marks of struma in the neck, which had evidently occurred in childhood. The point, too, of which I speak—that is, the close connection between typhoid fever and the strumous diathesis—may be seen in a still more striking light. I have been asked to see a case of this fever where, on inquiry, it turned out that two years previously the patient had symptoms of phthisis, including spitting of blood, and I have had to treat typhoid in a patient whom I knew at the time to be laboring under well-marked tubercular phthisis. In this view of the question the similarity of the lesions which occur in tubercular phthisis and enteric fever must not be forgotten; to me they seem to be of the closest."

In a discussion on this paper, Dr. Doyle, of Dublin, expressed the opinion that there is much resemblance between the characteristic appearances of the ilium in typhoid, and the characteristic local sores in syphilitic disease. Another point is that syphilitic ulcers occur in the intestines.

The Galvanic Bandage in Hydrocele.

In February last, Mr. S. Osborn read before the London Medical Society notes of two cases of hydrocele cured by single tapping, with the subsequent use of the galvano-suspension bandage. The first was a case of hydrocele of the tunica vaginalis, which had been present for seven or eight years; and the second was a case of double encysted hydrocele, present for six years. Both patients were affected with rupture on the same side as the hydrocele, showing a preternatural weakness of the parts in the vicinity. The ages were seventy and sixty-three, respectively. After tapping and manipulation the galvanic suspensory bandage was applied. The galvanism was believed not only to cause contraction of the muscular fibres of the scrotum, but to impart a healthy action to the serous sac, aiding absorption. Mr. Osborn recommended a trial of this bandage in other diseases of the testicle, such as varicocele and neuralgia testis.

Sustained Elastic Pressure in Chronic Uterine Inversion.

At a meeting of the London Obstetrical Society, Dr. Aveling reported this case:—

S. B., æt. twenty-nine, had a child two years ago. Delivery was followed by great bleeding, and metrorrhagia had continued more or less ever since. On admission a tumor was felt in the vagina, as large as a turkey's egg. A ring encircled its neck, but the sound could not be passed more than a line or two above this. On April 28th, Dr. Aveling's double-curved repositor was applied and adjusted by Dr. Aveling. After twenty-four hours the strings were tightened, the patient being very comfortable. About sixteen hours later she felt great relief; something had given way, and the strings had become loose. On examination the repositor was found within the uterus, high up, and was removed without difficulty. The uterus was completely restored.

Dr. Aveling stated that since he had invented his repositor, last year, five cases had been successfully treated by it.

The Increase of Accidental Deaths.

A recent English author, Mr. Walford, lately reviewed the numbers and causes of deaths of this class from the earliest periods at which records existed in Great Britain, bringing them down also to the latest date, and noting the circumstances which had helped to increase them, and also those which had a retarding influence. Mr. Walford is of opinion that these statistics show that violent deaths of various kinds have advanced with the progress of civilization. New forces, as also increasing mechanical productiveness, render the risk to life and limb continually greater. The five great divisions in deaths of this class are those caused respectively by railways, in the working of mines, by mechanical injuries, by chemical fumes and compounds, and by asphyxia (or stifling and drowning).

Here is a wide field for sanitation in rendering these forces less dangerous.

Hot Baths in Asphyxia of the Newborn.

In a communication to the Académie des Sciences, M. Goyraud calls to mind that M. Gustave Le Bon, in a note published in the *Comptes-Rendus* of 1872, indicated as a certain method of recalling to life young animals which had become asphyxiated the plunging them into a bath the temperature of which was gradually raised from 38° to 48° Cent. M. Goyraud has recently had occasion to employ this means for a newborn infant which had been delivered by the forceps. When the infant was extracted, the movements of the heart had entirely ceased, and various means for restoring animation, including artificial respiration, were persevered in for nearly two hours. No sign of life appearing, the infant, already become cold, was plunged into a bath heated from 45° to 50° Cent. (113° to 122° Fahr.). Thirty seconds had hardly elapsed when the first inspiration was observed to take place, and was quickly followed by free respiration, the infant in the course of five minutes having become full of life.

Chromicized Catgut Ligature.

In a recent lecture in Glasgow, Dr. Wm. MacEwen said:—

Carbolized gut softens, and yields in about forty-eight hours, and therefore in certain cases it may be necessary to use a ligature which would maintain its constricting force for a longer period.

With a view of obtaining a ligature which would serve this end I made, during the past few years, a series of experiments with catgut prepared in chromic acid and glycerine; and without going into detail concerning these investigations, it is sufficient to say that ligatures were obtained which admirably serve the purpose for which they were intended. They are prepared by making, first, a watery solution of chromic acid, one to five; then one part of this solution is added to twenty of glycerine. This forms a dark greenish compound, in which the hanks of catgut are inserted and retained for seven or eight months, the bottle containing them being occasionally shaken. At the end of this time the catgut acquires a semi-translucency, and has a dark color like preserved ginger. It is then ready for use, and is stored in a solution of carbolic acid and glycerine (one to ten). The size of the catgut which is of most use in the ligation of large arteries (excluding such as the innominate) is the medium, and this size has been very frequently tested since 1877. In the shape of deep sutures, this gut has been, and, as you see, is daily being used in the wards. In this way we are enabled to ascertain its behavior while in contact with the living tissues, and it has been very satisfactory.

The "St. Gothard Tunnel" Disease.

The workmen in the St. Gothard tunnel have been subject to an intractable, fatal anæmia, which destroyed many and puzzled the physician. At last, its nature has been discovered. It has been definitely traced to the fatal influence of a parasitic, nematoid worm, very prevalent in hot countries, especially in Egypt, where it causes the disease known as "Egyptian chlorosis." The presence of this noxious worm was only lately recognized as the cause of the cases of debility and impoverishment of blood epidemic among the workmen. How it was introduced there is not known. The ova develop out of the body and are taken in in the drinking water. The parasite in question is the intestinal leech, the *anchylostomum intestinale*. It is not wholly unknown in this country. See the MEDICAL AND SURGICAL REPORTER, vol. xli, p. 40.

Benzoate of Soda in Rheumatism.

A number of cases of acute rheumatism treated with benzoate of soda are detailed in the *Brit. Med. Jour.*, March 5, by Dr. David Macewan. The dose given was fifteen grains every three hours. The results were quite gratifying, and seem to promise that this drug will prove a remedy of considerable efficacy in the treatment of this painful disease.

Special Reports.

NO. IX.—OPHTHALMOLOGY.

BY C. S. TURNBULL, M.D.

(*Continued from page* 416.)

Holmgren observed in a decapitated criminal contraction of the pupil five minutes after the execution, and dilatation of the pupil only after two minutes more (Upsale Läk. Förk., 1879).

Berlin, in referring to *Anomalies of Refraction and Accommodation in the Eyes of Animals*, says:—

"In a large number of different domestic animals the refraction was mostly hypermetropic. Myopia was sometimes found in horses. In most of the larger animals irregular astigmatism of the lens could be demonstrated (Ophth. Section der Naturforscher-Versammlung in Baden-Baden, September, 1879, Z. M., 1879, p. 493).

Malarewsky, at the meeting of the Russian Society for Hygiene, spoke of "*A Page of a Book and its Influence upon the Scholar.*" He recommends to print white letters upon black background.

Becker contributes a case of congenital, one-sided, total color-blindness (A. f. O., vol. xxv, 2). This first accurately and fully-examined case of monolateral color-blindness refers to a girl of 17, in whose family there were color-blind males.

Bribosia found that among 825 persons, about three per cent. were color blind.—Internat. Med. Congr., Amsterdam, Z. M., Vol. xvii, p. 406.

Burnett gives us the *Results of an Examination of the Color-sense of* 3040 *Children in the Colored Schools of the District of Columbia* (A. O., Vol. viii, p. 191):—

Among 1691 colored girls, two were color-blind—0.11 per cent.; of the 1349 colored boys, 22 were color-blind—1.6 per cent. Compared with the percentage of color-blindness in school children, found by Magnus, the negroes show a smaller percentage of color blindness.

He has also devised *a Systematic Method for the Education of the Color-sense in Children* (Washington, September 25, 1879):—

He comes to the following conclusions: "The reduced color-sense, which does not depend upon an abnormal structure of the color-perceiving apparatus, but only upon an insufficient development of a dormant force, can be sharpened by systematic education. The really color-blind patient can be improved by training, but it may surely be expected that by practice continued during several generations, the tendency to color-blindness can be considerably weakened. Burnett's system of training is essentially only a modification of the one proposed by Magnus. The colors which Magnus prepares by lithography are furnished by colored worsted, which are arranged on a plate."

Dr. S. M. Burnett strikes the key-note in suggesting the education of the color-sense in children. The fact of want of education, *i.e.*, practice of the color-sense is, in our opinion, the sole cause of color-blindness, when other than a pathological symptom. Perhaps, too, some of the children might have been taking santonine as a vermifuge.

Cohn, in speaking of the *Quantitative Determination of the Color-sense in Europeans and Nubians* (Schles. Ges., Aug. 1, 1879; Schles. Zeit., No. 372, and Allg. Med. Centralzeit., Aug. 30, 1879), says:—

The color-sense of Nubians is normal, but their nomenclature is incomplete. Acuteness of sight much higher than 1.

Determination of the color-sense by direct sunlight, and by electric light (Ber. d. 12 Vers. d. Ophth. Ges. Z. M., Vol. xvii, p. 6). The distances at which most colors are recognized by electric light are considerably greater than by good daylight.

Gatschet, in speaking of *Adjectives of Color in the Indian Languages* (*The American Naturalist*, August, 1879; A German Translation in *Zeitch. f. Ethnologie*, Vol. xi, H. 4, u. 5), says:—

Seven Indian tribes of North America were examined with colored strips of paper. The expressions for green and yellow, red and yellow, yellow and brown, brown and red, were sometimes not distinctive by the Indians of North America as well as by those of South America; green and yellow were most frequently expressed by the same word. Otherwise the Indians distinguish very many shades of color.

Kotelman, by way of curiosity, notes that of the eyes of 9 Laplanders, 3 Patagonians, 13 Nubians, and 1 negro from the White Nile (*Berl. Klin. Wochenschr.*, 1879, No. 47), the color-sense was well developed; names of colors uncertain; acuteness of sight much greater than 1.

Manz mentions some of *the Effects of Fuchsine glasses.* (*Ophth. Section der Naturf. Vers. zu Baden Baden. Z. M.*, vol. xvii, p. 486). Green-red blind persons assort correctly with fuchsine glasses. The visual field for red is generally increased by a fuchsine glass.

Marty, on the question of the *Historical Development of the Color-sense* (Vienna, 1879), says:—

"Man is said to have had a sensation of color at all times; but lower classes of animals may gradually have gained the faculty of qualitative perception of light, and then transmitted it to succeeding generations. But to man, a gradual development of his judgment of colors, and an alteration of his sensation of colors, are accorded.

Netoliczka, in his "*Researches on Color Blindness and Myopia*," (28 Jahresber, d. Steir-

mærk, Laudes-Oberrealschule über das Studienjahr, 1878–79, Graz, 1879), says:—

"Holmgren's test is said to be the best. Among 1024 boys, 41 were color blind (completely and incompletely); in 31 the color-sense was reduced; 71 were not trained, that is, they sorted correctly, but only after some hesitation. The 283 girls had all a normal color-sense. The division into red-green and violet blindness is preferred. In 15 color-blind boys, Delbœuf's fuchsine stained glasses were employed, without, however, correcting the color blindness.

In PFLUGER'S remarks upon *Methods of Examination for Color Blindness* (*Vortrag auf der* IV, *Vers. d. Arzth. Centralvereins u. d. Soc. Méd. de la Suise, Correspondenzbl. f. Schweizer Aerzte, Vol.* IX), he says:—

Stilling's plates are entirely unreliable; also Cohn's embroidered plates. Daae's plates make rather high demands on the intelligence of the patient. Maxwell's disc is very desirable for the accurate study of a single case of color blindness, but it takes too much time for the examination of numerous persons. The polariscope can be recommended, but the instrument is too expensive. Holmgren's test and Pflüger's crape contrast method are best adapted for the examination of greater numbers. The methods in which spectral colors are used are especially suited to control examinations.

STEIN gives some interesting notes about the Nubians (*Frankforter Zeitung*, No. 213). They distinguish the ground colors, like the European, but they have no accurate and well trained color-sense, and an uncertain nomenclature. The acuteness of vision is more than double.

SWANZY says (Brit. Med. Assoc., Cork, Aug. 5–8, 1879; *Brit. Med. Jour.*, Oct. 4) that among 1230 males, 82, = 6.6 per cent., were color blind; among 90 females, not any. Holmgren's method was used. Nomenclature. (*Berl. Ges. f. Anthrop*, March 15, 1879. *Zeitcher f. Ethnologie*, 1879, Sept. 3, p. 146.)

VIRCHOW finds the color-sense well developed in the Laplanders, but they have a deficient nomenclature.

From Vol. IX, No. 4, of the *A. f. O.*, we note the following, by Dr. C. A. LAMBERT, of Goshen, Indiana, on "*The Treatment of Ophthalmia Purulenta Gonorrhoica, etc.*"—

"I can only offer as a commentary on the present general plan of treatment, whether the end sought is abortive or curative, to say, throw scarification, leeching and iced compresses to the four winds; they destroy five eyes where they save one. The trouble can be effectually aborted and cut short at pleasure, thus producing a speedy convalescence and cure. *I look upon these terrible disorders with as much complacency as I do on a simple case of acute catarrhal ophthalmia.* (Italics our own.) The principal points in this treatment, as outlined in the literature of the subject, I adhere to, such as maintaining the most scrupulous attention to cleanliness of cornea and ocular and palpebral conjunctiva, regulating the diet and habits of the patient, with perfect rest and repose of mind and body. The prescription I have learned to rely upon as almost a specific to the virus is as follows:—

℞.	Morphiæ sulph.,	gr.iij–v	
	Zinci chloridi,	gr.ij–vj	
	Aquæ rosæ,	gtt.x	
	Aquæ dest.,	℥j.	M.

In the case of ophthalmia neonatorum the remedy should be much weaker. I might incidentally remark that I have found this combination of equal importance in gonorrhœal urethritis, without the internal administration of any remedies whatever, excepting in the case of general debility. In many cases there was no discharge after the first injection. Patients tolerate this injection as they would so much water."

We would consider it criminal negligence "if we looked complacently upon" either a case of blennorhœa of the new-born, or gonorrhœal ophthalmia in the adult. Statistics go to prove that these sort of cases form a large majority of the whole number of eyes annually lost. Our advice to all those who have had but a limited experience in the treament of leucorrhœal or gonorrhœal ophthalmia, is to regard such inflammations as most threatening from the onset. *There is no specific treatment* for such. Save the eye, and protect its fellow from inoculation by all the laws of hygiene and surgery you can couple with your common sense and experience, just as in the treatment of similar vaginal or urethral inflammations. Eyes are lost by necrosis of the corneal tissue, which breaks down, for want of vitality, because of the strangulating swelling of the palpebral and ocular conjunctiva. What is still presented and recommended by many of the eminent teachers in our medical schools, especially by the very men who decry specialists? "*Drop into the eye astringent solutions of varying strengths of nitrate of silver, sulphate of zinc*, etc." Do not do it. You are acting the part of a coward. Hitting the poor eye when it is down. Take the advice of those experienced, and you will save eyes. We repeat, for the sake of emphasis, what Dr. Lambert says truly (*note the cause of his success*), "maintain the most scrupulous attention to cleanliness of cornea and ocular and palpebral conjunctiva, regulate the diet and habits of the patient, with perfect rest and repose of mind and body." We add, regulate your assistants, and nurses as well. They must expect no rest, or repose of mind or body. Eternal vigilance until the acute inflammatory stage be passed! Ice, and nothing but ice, will

allay the intense inflammation, and it must be withdrawn just so soon as the inflammation commences to subside. Herein lies the secret of the successful use of ice. Never put strong astringent collyria into the patient's or nurse's hands for use. Use them yourself, once or twice daily, *everting the eyelids and making the applications to the palpebral conjunctiva only*, being careful to wash them off before the everted lids escape. Alum, sulphate or sulpho carbolate, or *chloride of zinc*,* may be used as weak washes, but not dur ing the acute stage. We prefer the pure muriate to the sulphate of morphia and solutions of alum. Long naps are not desirable, either in the case of children or adults, as a good night's rest has cost many an eye. Eternal vigilance, to constantly cleanse the parts, is the watchword! Assist nature in every way, and do not "look complacently upon these terrible disorders" which contribute so largely to the blind in our asylums. We cannot do our whole duty, while mentioning this favorite subject, without referring those interested to a recent paper entitled "*Acute Suppurative Inflammations of the Eye*," by Dr. S. C. Ayres,† of Cincinnati.

From Dr. S. M. Burnett's next "Quarterly Abstract (*A. f. O.*, Vol. xi, No. 4) we call attention to a paper on the interesting subject of

Cross-eye; its Origin, Prevention and Treatment. By John Green. St. Louis *Medical and Surgical Journal*, August 5th. G. points out the cause of convergent squint to be a disturbance of the normal relation between accommodation and convergence, and suggests as an important therapeutic measure, particularly in the early stages, a paralysis of the accommodation by a mydriatic, the paralysis to be continued for months if necessary—the accommodation being supplied by means of convex glasses. He reports important results from the method in his practice.

A Case of Marked Intoxication, with Delirium, from the Use of Duboisin. By C. J. Lundy. *Michigan Medical News*, August 10th. The quantity of the drug used (by instillation) could not have exceeded $\frac{1}{50}$ of a grain.

On Affections of the Eye Consequent upon Whooping Cough. By Dr. M. Landesberg. Medical and Surgical Reporter, Sept. 18th, 1880. Four cases in all. In Case 1 there was serous infiltration of the retina, right eye somewhat swollen, macula lutea red, arteries thin, veins engorged. The two upper arterial branches were found to be permanently obliterated, and V. was reduced to $\frac{15}{36}$. In Case 2 there was complete exophthalmos of the right ball. In Case 3 there was ecchymosis in the retina. In Case 4 there was a subluxation of the lens in R. E.

A New Mydriatic. By H. S. Schell. Philadelphia *Medical Times*, October 6th. Schell has made eleven experiments with the homatropin hydrobromate, and deduces the following conclusions: Homatropin hydrobromate is not well adapted to the treatment of inflammatory or traumatic affections of the eye, on account of the conjunctival irritation it produces. It is especially adapted to the production of that temporary dilatation of the pupil and paralysis of the ciliary muscle which is so often required in examining the condition of refraction. The best solution to use is one containing 16 grains to 1 fl. ℥ aq. From 1 to 5 drops of such a solution may be required to produce the desired effect, according to the strength and activity of the ciliary muscle. Under the influence of a full dose the pupil attains its maximum dilatation in about twenty minutes. With a full dose the accommodation begins to fail in about ten minutes, and is usually totally suppressed in half an hour, although exceptional cases may require an hour. The total suppression lasts about three hours; the accommodation then gradually recovers itself, and is fully in action again at the end of ten or thirty hours from the time of last instillation. The local action of the mydriatic is not accompanied by any unpleasant effects upon the general system.

A Case of Basedow's Disease (Exophthalmic Goitre), Terminating in Total Loss of Sight from Inflammation of the Cornea. Dr. H. G. Cornwell. *American Journal Medical Science*, October.

The cause of this rare result of Basedow's disease C. thinks is due, 1, to exposure of the eyeballs to the air, and wholly disassociated from any affection of the fifth pair or ganglion of Gasser; 2, to the affection of the tropic nerves *alone*, rendering the eye unable to resist the injurious influences of the air, dust, etc.

Reflex Aphasia from a Glaucomatous Bulbus. By A. Wanstall. *Trans. Am. Homœop. Oph. and Otol. Soc.*, 1880.

This is an interesting case to the neuropathologist as well as the oculist. From the clinical history, which is given in detail, it appears that a marked aphasia, which was the concomitant of an eye trouble in which there was + tension (whether primary or secondary is not clear), was thoroughly dispelled after an enucleation of the ball.

(*To be continued.*)

—A verdict was recently rendered in the District Court of Erie, Pennsylvania, against Dr. A. S. Lovett, in a suit for malpractice, for $2450. The trial lasted two weeks, and the jury remained out twenty-four hours.

* We have used the solution as recommended by Dr. L., of zinci chloridi, in two cases of gonorrhœal ophthalmia, and have found it most grateful to our patients, and no doubt a most valuable application, and as an astringent wash, *after the acute stage has passed*, to be particularly recommended. The same solution, as an injection, at the same time, cured the urethritis in each case.

† The Cincinnati *Lancet and Clinic*, Feb. 12th, 1881.

Correspondence.

Danger of Dusting Calomel into the Eye.

Ed. Med. and Surg. Reporter:—

I see, by the London *Lancet*, for February, 1881, that Dr. Henry Faulds, of the Tokio Hospital, claims to have made a discovery in the treatment of pterygium by the daily dusting of calomel dust into the eye.

The Doctor is not correct in having anything new in the treatment, although it is not generally laid down in the text-books upon eye disease, for I have dusted calomel into the eyes, not only for pterygium, but for granular lids, when there was little or no purulent discharge. And when a patient comes to me with a foreign substance in the eye I never allow them to leave the office until I have dusted some calomel into the affected eye, and such has been my practice for the last six years, with the most flattering success.

I find that the daily dusting is rather too much of an irritant, and that cases do better to only dust the eye every other, or even skip two days between the dustings. I have a patient who had very severe chronic granular ophthalmia, with a cloudy cornea, who has used the calomel for more than a year with no injurious effects whatever; still, I think that all practitioners who dust calomel into the eye should heed the suggestions of Dr. Schlæfke:—

1st. Where a patient is taking iodide of potassium internally, the local application of calomel to the eye excites an acute inflammation.

2d. Iodide of potassium when taken internally is rapidly disseminated through the organism. It appears in the secretions, where its presence can be detected in a few minutes.

3d. When the iodide is given in doses of six grams twice daily it is always found in considerable quantities in the tears.

4th. Although calomel is only very slightly soluble in water, it is ten times more soluble in a solution containing seventy-five per cent. of the chloride of sodium.

5th. When dusted on the conjunctiva calomel is rapidly dissolved, and exercises a chemical action.

6th. If it is thus employed while the patient is taking the iodide of potassium, the iodide and biniodide of mercury are formed in the tears, and these caustic substances cause inflammation.

Thus care should be exercised, especially in old syphilitic subjects, who are liable to take iodide of potassium at any time.

Hoping that some one may profit by these suggestions, as I have done, I send them to your valuable journal E. W. Hill, M.D.

Glens Falls, N. Y., March 24th, 1881.

Large Amount of Opium to a Child.

Ed. Med. and Surg. Reporter:—

About noon, 28th ult., a man came to my office in breathless haste, asking me to go to his house, distant about five miles, saying, "the baby had the stomach-ache this morning; my wife gave it some laudanum and cannot waken it." On my arrival I found a babe (eight months old that day) lying in the arms of its almost frantic mother, pale, comatose, bathed in perspiration, extremities cold, slow, feeble pulse, and pupils contracted to the size of a very small pin-head. Noise, rough handling, and dashing cold water in its face utterly failed to arouse the child. I was told the child cried hard that morning, hindering the mother from doing her work, and she gave her a dose of laudanum about 5 o'clock, and another about two hours later. It was then 1 P.M. I asked how much she gave, and she said she did not know. "Surely," said I, "you know whether it was four, six, or ten drops." "But, Doctor, I did not drop it." Finally she told me the first dose was half a teaspoonful, and the last one all the teaspoon would hold. I carefully measured the teaspoon, and it held two drachms. On my expressing surprise that it had not killed the child outright, she said she had often given it half a teaspoonful. Her husband brought from the pantry a three-ounce vial, containing less than one ounce of laudanum, and informed me that that was the fifth vial of laudanum of that size which had been given to the child; making fourteen ounces of laudanum administered to a child during the first eight months of its life. To resuscitate the child seemed a hopeless task. I gave five drops fluid extract of belladonna and a teaspoonful of whisky, in a little water, which with difficulty was swallowed. I then vigorously spanked the child, at first with my hand and afterward with a ruler, until the buttocks were intensely reddened, before I could arouse it sufficiently to emit a cry. I worked at it in this way, at intervals, for more than two hours; kept it awake by noise, dashing cold water in the face, and shaking it, but when these means failed and it sank into a deep sleep, I had recourse to the ruler. The next day the child appeared well, excepting being somewhat dumpish. Instead of the child being constipated by such enormous doses of laudanum, it has always been troubled with diarrhœa. I will only add that the laudanum was all purchased at a first-class apothecary store, and was a reliable article.

T. C. Wallace, M.D.

Cambridge, N. Y., April 4th, 1881.

London International Medical and Sanitary Exhibition

Ed. Med. and Surg. Reporter:—

Sir—We have much pleasure in announcing that arrangements have been completed for holding the International Medical and Sanitary Exhibition initiated by the Executive Committee of the Parkes Museum of Hygiene.

This Exhibition will be held on the occasion of the Meeting of the International Medical Congress of 1881, and will be open from July 16 to August 13.

The Exhibition will comprise everything that is of service for the *Prevention*, *Detection*, *Cure* and *Alleviation* of Disease, and will be divided into three sections.

Medical Section.—Surgical Instruments and Apparatus; Appliances of the Ward and Sick-

room; Drugs, Disinfectants, Medical Dietetic Articles and Mineral Waters; Electrical Instruments and Appliances; Microscopes and Optical Apparatus; Apparatus of other kinds used in the Investigation of Disease: Appliances used for the treatment of Sick and Wounded during War; Street Ambulances, etc.; Appliances used in Teaching Medicine; Books, Diagrams, Models, etc.

Sanitary Section.—Domestic and Hospital Architecture; Planning, Construction, Decorative Materials; Ventilation, Lighting, and Warming; Water Closets, Sinks, Baths, etc.; Sewerage and Drainage; Water Supply and Filtration; Health Resorts and Sanitaria; Books, Diagrams, Models, etc.

Miscellaneous Section.—Applications of hygienic principles to Food and Dietaries, Clothing, etc.; School Furniture and other articles more or less connected with the general purpose of the Exhibition.

The Exhibition will be held at South Kensington, space having been granted for it by the Royal Commissioners for the Exhibition of 1851. Applications for space from Great Britain and Ireland, and the Continent of Europe, must be made not later than Thursday, March 31, 1881; but applications from India, the Colonies, and America, will be received up to April 16, 1881.

Certificates of Merit will be awarded to Exhibitors. New inventions exhibited will be protected under a certificate from the Board of Trade. Exhibitors will be charged for space, and it is hoped that the Exhibition, in this and other ways, will be made to pay its expenses. An undertaking of this magnitude, however, is not without risk, and although upward of £800 have been subscribed as a Guarantee Fund, we hope the committee will receive such additional contributions as will enable them to thoroughly carry out their work. A list of the guarantors will be published in the catalogue.

Forms of applications for space, and all particulars, may be had of the Secretary of the Exhibition Committee, *Parkes Museum of Hygiene, University College, London.* Office hours, 10 to 4; Saturdays, 10 to 2.

We are, Yours, etc.,

JOHN ERIC ERICHSEN, F.R.S.,
(*President of the Royal College of Surgeons*),
Chairman of the Exhibition Committee.

MARK H. JUDGE,
(*Curator of the Parkes Museum of Hygiene*),
Secretary of the Exhibition Committee.

Parkes Museum of Hygiene, University College, Gower Street, Feb. 22, 1881.

NEWS AND MISCELLANY.

An Anatomical Act in Michigan.

Our Michigan exchanges give us the new Anatomy Act of that State, which has recently become law. Under its provisions the Demonstrator of Anatomy in the University of Michigan, at Ann Arbor, is made receiver and distributor of the cadavers from the prisons and poorhouses of the State. Unless the body is claimed within thirty-six hours after its decease the keeper of prison or poorhouse shall ship it to the University dissecting rooms, where it shall be properly "embalmed or put in a state of preservation," and be still subject to the claim, on the payment of expenses incurred, of relatives or legal representatives for ten more days. At the expiration of this time bodies thus received "shall be used for the advancement of anatomical science in the State and in the following institutions of learning only, viz: The University of Michigan, the Detroit Medical College and the Michigan College of Medicine. And the said bodies shall be distributed to and among the same equitably, and in the order in which they are received, and the number assigned to each by said demonstrator of anatomy shall be proportional to that of its students in actual attendance. And each of said institutions shall pay quarterly to said demonstrator its ratable proportion of the expenses borne and incurred under this act."

The expenses incurred will consist of a sum not to exceed fifteen dollars, which the demonstrator shall pay the keeper of the poorhouse or prison for each body received, to cover the expense of boxing and shipping, and the cost of "embalming or putting in a state of preservation."

The Act apparently gives satisfaction to the parties most interested.

Motion and Rest.

At a recent lecture at the Franklin Institute of this city by Mr. D. S. Holman, he instanced charcoal as a full and apparently inert substance, but when it is powdered, mixed with water and placed under a microscope of a thousand diameters, by which each particle or atom is magnified one million times, we can see the vibratory motion of the atoms. This is equally true of every substance which we can reduce to powder and suspend in clear water, and this motion of atoms is continuous and perpetual. He undertook to show that these particles were absolutely running in a piece of iron, or in corundum, the hardest substance known, after the diamond.

Motion is always indicated by temperature, and when it becomes sufficiently rapid, the atoms fly apart, and the matter becomes liquid and then gaseous. The term solid is a misnomer, for, in fact, a mass of cast-iron is nothing more than a mass of jelly—and this never ceasing motion is an absolute property of not living matter—and there is no such thing in the universe as absolu e rest.

Examination for the U. S. Marine Hospital Service.

A competitive examination will be held in Philadelphia, to fill three vacancies in the position of Assistant Surgeon in the U. S. Marine Hospital Service, on April 25th. Candidates must be between 21 and 30 years of age, and graduates of a regular medical college.

Medical gentlemen desiring to apply for examination should make their application to "Supervising Surgeon-General, U. S. M. H. S., Washington, D. C.," without delay.

How "Free" Quinine Works.

We clip the following extract from the *North Carolina Medical Journal*, and recommend it to the consideration of an editor in the State immediately west of North Carolina:—

"We have been favored with the Annual Review of the Drug Trade of New York, for the year 1880, by D. C. Robbins, Esq.

"It is shown in the review of the importations and value of cinchona barks for 1880, that they were of inferior quality.

"It is remarkable, also, that the price of quinine to the consumer has increased since the duty on it has been removed. We believed, at the time the American Medical Association was so zealous in bringing about the abolition of import duty, at Atlanta, that it was a hasty and ill-advised step, and we voted against it.

"As the matter now stands, Congress can do no less than remedy the mistake by removing the tax and duty on material concerned in the manufacture of quinine."

The Promises of the Sick.

In a case tried at Paris, where a surgeon claimed 6900f. for thirty-one dressings of a wound and for accessory expenses, the Court ruled that "there could be no valid agreement between the patient and his doctor, for the former, struggling for his life, is no longer master of his will, and if he makes any agreement it is only fear and necessity that guide his will.

Personal.

—Dr. Charles K. Mills has been appointed Lecturer on Mental Diseases in the Medical Department of the University of Pennsylvania.

Items.

—The Cleveland Medical College and the Medical Department of the University of Wooster, located at Cleveland, are about to be united into one Medical College. Hon. H. B. Hurlbut has given $20,000 on condition that this be done, and the authorities of both colleges have decided to unite.

—Rev. T. B. Miller, who sprang into public notoriety some time ago, through his connection, as "Dean," with the Philadelphia College of Medicine and Surgery, a bogus institution located on Tenth street near Race, and Dr. Isaac J. Hathaway, of this city, were arrested, April 5th, on the charge of criminal malpractice on a young woman, and were bound over for trial.

—M. Menier, the famous proprietor of the "Chocolat Menier," recently died in Paris, at the age of fifty-five years. He was at one time the leading wholesale druggist of Paris, and he had one of the finest private laboratories in the world. For years he had spent large sums in endeavoring to discover a practical method for the synthetic production of quinine and morphine.

—A meeting in aid of the fund to supply raised letter books for the blind was held in Boston, April 1st, and considerable money was subscribed. The intention is to raise a permanent fund of $75,000. Miss Laura Bridgman, the celebrated deaf, dumb and blind girl, was present at the meeting, and read from one of the prepared books of the Scripture, the passages being traced by her with the fingers of one hand and communicated by the fingers of the other to an interpreter who spoke them to the audience.

OBITUARY NOTICES.

—Dr. William H. Phibbs, surgeon of the Inman steamship City of Richmond, died in New York, on April 3d. Dr. Phibbs was thirty-four years of age, and for a number years had been in the employ of the Inman Line, and had borne a high reputation.

—Dr. Josiah Hornblower, a well-known and highly respected physician of Jersey City, died April 3d, at his residence, at the age of 71 years.

QUERIES AND REPLIES.

Tripolith.

Dr. Sanford, N. Y.—Tripolith is a secret preparation manufactured by a firm in Switzerland, principally for stucco work and other uses to which plaster of Paris is put. It has been adopted for surgical splints and jackets by various German surgeons.

Dr. W. H. K., of Ohio, asks how may a solution of atropia for hypodermic purposes be kept for some length of time without becoming unfit for use.

Ans.—Prof. Gubler (*Therapeutics*, pp. 176-8) discusses the injury to hypodermic solutions arising from keeping, and traces them to either crystallization or the development of algæ The latter can be prevented by the addition of one of the anti-zymotics; the former only by re-dissolving.

Dr. S. J. R., of Pa.—We mention Liddell, on Apoplexy, $4.00; Erichsen, on Concussion of the Spine, $2.25; Charcot, Localization of Brain Disease, $1.50; as possibly what might suit you.

Dr. C. C. S., of Ala.—The abuses of medical charity have been discussed in various medical journals, but we know of no separate publications on the subject. Should our subscribers know of any, they will confer a favor by sending in the titles.

MARRIAGES.

SIMSOHN—STERN.—On April 6th, by the Rev. Dr. S. Hirsch, Jos. S. Simsohn, M.D., and Miss Clara, daughter of Mr. Morris Stern, all of Philadelphia.

STEIN—KAUFMAN.—On Saturday, April 9th, at the residence of the bride, by the Rev. Dr. Eccleston, Gottlieb Stein, M.D., and Catharine Kaufman, daughter of the late William Kaufman, all of Stapleton, Staten Island, New York.

DEATHS.

GAINES.—At Boonton, N. J. March 31st, Dr. E. B. Gaines, in the 90th year of his age.

HORNBLOWER.—Jersey City Heights, April 3d, Dr. Wm. Hornblower, aged 71 years.

MORRIS.—On March 29th, 1881, at Norristown, Pa., in his 74th year, Dr. Sidney R. Morris, formerly of this city.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1215-1267eow ROBERT SHOEMAKER & CO.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

DISEASES OF THE HEART—CONTINUED.

BY ALONZO CLARK, M.D., LL.D.,

President and Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

I propose to show you some illustrations of the dilated heart, or dilatation of the heart. This is, probably, as good a specimen as you will ever come across of dilatation affecting all the cavities of the heart. Dilatation may affect but one cavity, or as in this instance, involve all of them. Here is the right cavity, and it is stuffed with hair, to keep it in shape. You will see the thinness of the walls there, and here on the left side you can see it for nearly the whole length of the ventricle. You observe it is very much increased in bulk, apparently, but, of course, very much diminished in weight. This plate represents dilatation of the heart and aneurism. Perhaps you never heard of aneurism of the heart, but there is a thing that is called by that name. Here you observe is marked dilatation of the ventricle, and here is a little dark cone on the top of it; that is a yielding of the heart's wall, and makes, strictly enough, an aneurism, and at last would, if the patient had not died of something else, have ruptured.

Here is a specimen of ruptured heart. It is fatty. The right side is ruptured. In this plate is represented dilatation of the heart, with aneurism on its top, and rupture of the heart. Here are two specimens, I will not say of domestic manufacture, but that have occurred to me. This particular one is the result of a kind of ulceration. I shall explain that to you, probably, in the course of the hour. A part of the heart's structure has been removed. It looks exactly like an ulcer, and in that weakened spot the heart gave way. This, again, is upon the right side. Now, here is fatty degeneration that has weakened the walls of the heart, and it has given way suddenly, and produced, of course, almost instantaneous death.

Before I go on with the matter of rupture of the heart, it is probably best that I give you a few statistics from different authors referring to the frequency of disease in the several valves of the heart. Here, for example, in 300 cases of endocarditis in the adult, 297 were on the left side, 32 on the right side; 268 were confined to the left side, 3 confined to the right side; 29 in both. (Taken from statistics.) In the fœtus and newborn child, the evidence of endocarditis was in 192 cases in the right side, and in 15 in the left. Observe the very marked disproportion between the adult record and the infant record: 192 in the right side in the infant or newborn, 15 only in the left; in the adult 297 out of 300 cases on the left side, but 29 of these were on both sides at the same time. In regard to the particular valve that is most liable to disease, in the 300 cases 255 were in the mitral; a portion of these were in the aortic also, as you will see further on; 129 aortic; in the tricuspid valve, 29; in the pulmonary valve, 3; or one in a hundred. Of these 300, 159 were of the mitral only; 40 were of the aortic valve only; 3 of the tricuspid valve only; and none of the pulmonary valve only.

Here, I have a record obtained from Bouillaud; and observe it is in hospital practice, for children in Paris are sent to a hospital separate from the

general hospital. He found endocarditis occur in 55 per cent. of cases of articular rheumatism. Budd, an English physician, finds it in 48. Fuller, in 23. Wunderlich and Lebert, in 23 per cent. in a hospital for adults.

In regard to embolism, of which I have said something to you, in endocarditis or after it, different parts of the body are the seat of embolism, or parts that obstruct the flowing mass: In 84 cases that were observed in the Berlin anatomical museum, 57 were of the kidneys, but not of the kidneys alone; the kidneys were the seat of embolism in 57 out of the 84 cases. But these emboli are not always single; the spleen was the seat of the same accident in 39 of the cases; the brain in 15 cases; the liver and alimentary canal in five cases only out of the 84; and the vessels of the skin in 14. Of course, in several of these cases the emboli were multiple; that is, different organs being affected at the same time.

Now, with reference to rupture of the heart—which subject we began, but made little progress in it—I told you then, I think, that I do not believe the heart is ever ruptured when it is in a sound condition. You have just seen some illustrations of rupture of the heart, but bear in mind that some previous disease may have existed; it may be there was what they call myocarditis, a form of disease that I have not yet described to you. That produces, as you will see when I shall describe it, a weakening of the muscles here, and makes a place of least resistance, and a place that is liable to give way under the power of other portions of the heart. The specimens that you are examining show fatty degeneration, or rather adipose degeneration, a weakening of the muscular tissue; and through perhaps the middle or one side of this adipose deposit the blood may make its way by rupture of the muscular tissue, for fatty tissue has little consistency, gives but little resistance to the power that is acting on it. Now, if you had the means of determining in what particular cases this adipose degeneration of the heart has occurred, you might anticipate such an occurrence, or rather, you might conjecture that it might occur. And that is about as far as you can go in the diagnosis. I told you when we were last together, that we have no means of diagnosticating fatty degeneration of the heart. You observe in these figures that the organ is not enlarged; you therefore gain nothing by percussion. There is no valvular sound to indicate the presence of any new structure; therefore, auscultation amounts to nothing. The heart beats naturally and easily until the rupture comes. It may come during some period of considerable exertion, and the first you know of it is sudden death—and then you do not know what is the cause of death until you have made a post-mortem examination. So that speculation in this direction is really a loss of time. You can, in the language of Goldsmith, be sure, after she is dead, that her last disorder was mortal, and that is about all you can say. "The doctors found, when she was dead, her last disorder mortal." The accident may surprise you, then, at almost any time. Still, it is not a very frequent occurrence. When it occurs from a weakening of the walls of the heart, of the muscular tissue of the heart, from previous disease, other than fatty degeneration, it will be likely to take you by surprise equally, because there is no murmur, there is no friction sound, there is nothing that is unnatural in the action of the heart, unless, perhaps, occasionally a little feebleness which you can account for in a dozen other ways.

When it follows myocarditis you have no means of anticipating it. It is, then, practically a post-mortem disease, and you can prescribe no treatment.

Now, a few words about myocarditis; and the first word I have to say is, that it is a tautology. We duplicate upon muscle. Still, it is a term that has become current, and we must meet it as it stands. The term means an inflammation of the muscular structure of the heart, and I am a good deal in doubt whether it is really an inflammation.

There you observe, in this upper figure, a very marked change in the walls of the left ventricle. Myocarditis produces at first a little reddening where it is located, and afterwards it comes down to about this color. The disease is local; it does not affect the whole heart at the same time. It may be a spot that you can cover with the end of your finger—at any rate with the palm of your hand—rarely larger. Here is a heroic sort of thing. I ought to have shown it to you before. It is a heart ruptured where once fatty degeneration occurred. Upon its exterior here is a spot of myocarditis which has passed its active stage, and a material that I shall describe to you pretty soon has been discharged from the pericardium. If you lift this up you will see that there is a hole through the wall, and this again is in the right side—the effects of myocarditis, but not myocarditis itself.

The reason why I doubt whether the change that I am going to describe to you is the result of inflammation is, that so far as is known there are no general inflammatory symptoms; no par-

ticular increase in the frequency of the pulse; no known elevation of the temperature of the body. It comes on quietly, while the patient is attending to his business, and nothing is known of it really, except by conjecture. It is occasionally found to follow pericarditis and endocarditis. It affects, perhaps, one-half the thickness of the muscular structure of the heart, and may occur in the septum ventriculorum, or it may occur upon the exterior face of the heart, either upon the left or upon the right side. As it makes its progress the material that is effused is not pus. Examined under the microscope it seems to be made up of a transparent fluid and broken down portions of the heart tissue. It seems to be rather a breaking up of the muscles of the heart, and we can conceive that it may be by obstruction to the circulation of the blood to such particular part. When the disease is matured you find what you would call a little abscess, and what has always been called heretofore a little abscess; but the material, as I stated to you, that constitutes this apparent pus is not pus corpuscles, but debris. This material is so fine you can only recognize its quality by the microscope. It at length is discharged, either outwardly into the pericardium, or inwardly into the cavity that it may be affecting. If the latter accident occur, it may do mischief in the way of producing embolism in distant parts of the system. More frequently it is evacuated exterior to the heart and within the pericardium. And it seems to undergo absorption when it occurs there; is carried away, no remains of it being left. But after this evacuation of the debris of the muscular tissue, and to a certain extent of the connective tissue here, there is a chance for cicatrization. The connective tissue which covers the muscular fibres is of itself sufficient to start a healing process, and if the heart is not overstrained there may be a cicatrix formed over the depression; a cicatrix of fibrous tissue, which, of itself, gives strength to the weakened part of the heart. It may rupture before this cicatrix is formed upon it. When the heart has been in that way affected, and the cicatrization has taken place, you may examine it at post-mortem, and find that it has not ruptured, the cicatrix has been a protection against that; but you find a depression covered by a whitish connective tissue, which is sometimes of very considerable strength. This is, in substance, myocarditis. And you can see now how myocarditis, in the particular specimen I gave you last, may produce a weakening of the muscular structure, so that it can be ruptured. That, together with the effects of the debris, this mixed matter upon the circulation constitutes the whole of the bad history of myocarditis. There is a certain amount of inflammation of the heart itself when there is endocarditis and pericarditis, as I have already told you. The most common result of that, however, is simply an infiltration into the muscular tissue of some serum; a sort of œdema of the heart, which readily goes away after the inflammation has passed off. It is only in rare instances that this myocarditis occurs in the same relation; that is, in connection with endocarditis and pericarditis.

It occasionally happens that a part of the wall of the heart will yield to the contraction, or rather to the pressure of the blood upon it, and pouch out. You have a plate illustrating that now in your hands. That, however, was a thinning of an already thinned heart; a particular part was more thinned than the rest, and yielded, so as to allow a pouch to be formed by the blood within the cavity. More commonly these aneurisms, for they are so called, occur in the inferior and right portion of the left ventricle. It becomes pouched out toward the median line and downward. This occurs sometimes to a very considerable extent. And it will form clots, layers of coagulated blood, as they will form in an aneurism of the popliteal space, or in the aorta, or in any other part of the body. As the blood coagulates in this expanded portion it makes a covering which gives a certain degree of strength to this weakened part of the heart. After this has continued for a considerable time a something of a white color, thick and resisting, of the character of a cicatrix, forms upon it on the inside. But this is not a cicatrix, because there has been no ulcerative process. But here was a weakened portion of the heart, and nature seems to know how to fortify it, and on the endocardium there is thrown out a certain amount of lymph, which becomes organized, forms a new membrane of the connective tissue variety. You do not see that in this plate. You see only the layers that have been separated for the purpose of illustration; layers of coagulated blood that have been imposed and superimposed upon this weakened part of the heart, and they are torn off in such a way as not to show you exactly the relation to the heart itself.

We do not know much about this form of disease during life. It is, when found, almost always after death. We can find an enlarged heart, and from the extension of the enlargement in a particular direction we can infer that it is of the left ventricle, but we can hardly go beyond that. A distinct recognition, before death, of aneurism

of the heart as it usually presents itself is exceedingly rare. I had lately, within a year, I think, a very remarkable case of aneurism of the heart, expanding in an anterior direction, and pushing its way through the intercostal spaces between the fourth and fifth ribs. I am not quite sure that is the point. There was a very decided pulsation. It was a case in Dr. Cole's practice, and he called me in to see it, and I could not make anything out of it but aneurism of the heart. It could not have been aneurism of the aorta, because it was below the point that that aneurism occupies. It pushed the ribs forward a little, and formed a cone in the intercostal space, like that upon the heart already shown you. Dr. Cole watched this patient for some months, and he at length died suddenly, as persons with aneurism are apt to die; and Dr. Cole asked for a post-mortem. He could not get it. The friends would not consent to it. He went to the coroner, and the coroner came and inspected the body, and he said, "Oh, yes, this is aneurism. We know aneurism well enough. A post-mortem is not necessary." And then Dr. Cole resorted to the priest, and tried to induce the priest to persuade them to let such a curious thing be seen; but the priest, even, hadn't the power to persuade them, and the mystery was buried in the grave. Still, I can hardly entertain any doubt that it was of this kind. Cases of the kind, you may understand, are rare; still in the enumeration of diseases of the heart it seems important to say a few words, even of the occurrence of a rare one.

Now, then, I have something to say to you about the heart clot. No, not yet; fibrous degeneration of the heart comes before that, because it is of the heart structure itself. Dr. Quain, who gave us our first ideas of fatty degeneration of the muscular fibres of the heart, a few years ago, described what he regarded as hypertrophy of the heart arising from increase of its connective tissue. He called it fibrous hypertrophy. I have been, from the time he made this statement, a little skeptical in regard to the correctness of his opinion. But during the present winter I have examined by the microscope some specimens that are unquestionably of the character that he described, and a little further on, when you have fewer specimens to handle, I will show you some specimens under the microscope that will illustrate this form of disease. It seems that the connect ive tissue can take on hypertrophy by itself alone. The quantity of it that may be found upon the spleen, sometimes called a cicatrix, is enormous, and it is perfectly well formed connective tissue, with the fibres and with the nuclei, and it may be half an inch in thickness. The connective tissue in the liver is multiplied very much in certain forms of disease; the connective tissue in other parts of the body occasionally. But in the heart it seems to have had but a recent discovery. All the hypertrophies that have been noticed have been deemed to be hypertrophy of the muscular tissue only. As to the mode in which this particular form of disease presents itself under the microscope, when you make a section of an enlarged heart you follow the muscular tissue a certain distance, and then it breaks up, and in the place of it you find connective tissue, and the connective tissue may be wide enough to reach the whole breadth of the field of the microscope, and no muscular tissue in it. But you see muscular fibres ending, one here and another there, then gone, and then by and by they will be observed again, that is, at a little distance from where they disappeared. It seems then to destroy the muscular tissue when the hypertrophy of the connective tissue is marked. But frequently it seems to occur without being really a disorder. There is always between the layers of muscular fibre of the heart some connective tissue. The bundles are separated by something more than a myolemma, sarcolemma, or whatever name you give it; some real connective tissue thrown in between the sarcolemma of the different bundles of fibres. You see that, in passing a microscope over a thin section of the heart, in almost any instance. Well, this increase in quantity, of course, increases in thickness, and by just so much as it increases beyond a certain point it seems to diminish the muscular fibres by compression; that is, causes their absorption and removal. When, then, this form of disease presents itself in any decided manner, you can easily comprehend that you will have an enlarged heart with diminished power; this deposit is, for the most part, in lieu of, or a substitution for, the muscular fibres, and as it has no contractile force upon itself it will only diminish the strength of the heart. I do not know that we are advanced far enough in our knowledge of disease to distinguish between fibrous hypertrophy and muscular hypertrophy; it requires some further observation; but it is important that you know that there is such a thing as fibrous degeneration of the heart with increase in size. It is a matter that is open to study yet. The study has not been pursued far enough to enable us to lay down rules and principles in regard to it.

Now, then, we come to heart clot. I give a little time to the matter in the lectures, as I used to receive from the graduates of the college long letters in regard to it. I remember one, four sheets of foolscap, written on each side of the page, describing a something that was terrible. A clot had formed in the heart and extended out in the vessels about as far as the examiners could pursue them, and it was wonderful that a man could live with such a thing in his heart; well, he did not. All that formed after he died.

A distinguished physician of Philadelphia wrote a book on the frequent occurrence of ante-mortem heart clot. He thought they were of very frequent occurrence. I do not believe that. That clots can form in the heart previous to death, and may cause death, I fully believe, but the occurrence is rare. I will make you understand that, I think, before we get through. Now, to distinguish between the clot that is formed before death and one that is formed after, there are two or three rules that will be very diagnostic. You come to a heart, the left ventricle of which is filled with coagulated blood, and the blood runs on out through the aorta, and you can follow it to some of the ramifications of the large vessels; or it forms in the right side and extends through the pulmonary artery into even minute branches of the pulmonary vessels, and it does really look like a very formidable thing, and a person who does not understand it would assume that it was as bad as violent death. Now, then, if a clot form in the heart before the heart ceases to beat, it can never be attached to all the periphery of the heart. If the heart has ever beaten upon the clot that has formed in it, the contraction that must follow, if life continues, will separate the clot from all the external walls, from everything except the septum ventriculorum; and when clots are found in the heart that have been formed during life, they are always attached to the septum, usually to the lower part of the septum, where are the greatest number of pectean muscles. The very act of contraction must separate it. If you will think of it for a moment, you will see it cannot be otherwise.

These clots are of two colors, buff and black. The buff is uppermost with reference to the position of the body after death; the dark colored is the dependent portion. Now, what is that buffy coat? Exactly what takes place in the blood when withdrawn into a bowl and allowed to stand. The upper layer has been formed by the sinking of the blood corpuscles into the deeper layer, and that takes time. There is not time between two heart beats for anything of that kind to take place, and the occurrence of a clot with a buffy portion and a dark portion is conclusive evidence that the coagulation took place after death. The heart was full; it died expanded, and the coagulation took place in a manner that would require several minutes to form it, perhaps an hour or two. The blood does not coagulate quickly within the body. It has been estimated that it requires about six hours for the blood to become firmly coagulated after death. Sometimes it takes a much longer time than that, but a quick coagulation does not take place. As the blood corpuscles are a little heavier, under most circumstances, than the fluid portion of the blood, their specific gravity being a little greater, they have time to sink to the deeper portions of the pool of blood, and allow the surface to coagulate with a buffy coat, a yellowish, semi-transparent substance. That, then, is conclusive against the chances of ante-mortem heart clot.

It has been assumed, frequently enough, that the indentation of the clot at the point where the valves are placed is evidence of an impression made upon it by the action of the heart during life. But altogether another thing. When death takes place and the heart ceases to send a current of blood through the aorta, the upper portion of the valve of the aorta falls downward, of its own weight, into the blood; the lateral ones fall a little, but not so much. The anterior is the point where quite an indentation in the coagulum has been noticed; it falls into the fluid blood, and when the coagulation takes place, it will take place about that valve that hangs in it, and, of course, it will leave an indentation in it. So far from being an evidence of ante-mortem clot, that particular thing is evidence that it formed after death. Almost all the clots that are found after death are formed after death in the heart and great vessels.

If the clot has formed before death, and the heart has beaten upon it, it has been compressed, and will be found attached to the lower part of the septum ventriculorum, and not to the walls of the heart, unless it be the very apex. Clots are formed in the heart. Here is a figure of one, and you observe it is rather crab-like in form; it has several legs. We will continue this subject at our next lecture.

—In Kansas the new prohibition law not only forbids the use of wine in the sacrament, but imprisons for two years in the penitentiary the minister who so administers it, and shuts up the church itself as a public nuisance.

Communications.

CHIAN TURPENTINE, AND ITS EFFECT IN CANCER.

BY HUGO ENGEL, A.M., M.D., F.A.A.M.,
Of Philadelphia.

Cancer is a fearful disease, and especially so if it affects internal organs, as external cancer, if seen in time, may frequently be removed by operative interference, its recurrence sometimes prevented, or life often prolonged for many years, or at least made bearable. But internal cancer is a scourge for the human race. Here its removal by the skilled hand of the most daring surgeon can rarely affect more than to prolong a life, for a short period, which is inevitably doomed to be prematurely ended by the inexorable malady.* Always beginning insidiously, it leaves the patient unaware of its existence until it causes a certain train of symptoms which force the sufferer to seek the aid of a physician, whose grave diagnosis reveals, unexpectedly to the patient, the unavoidable fate that awaits the latter. The diagnosis of this fearful malady once made, death becomes only a question of time; not one of years—nay, of months only. And notwithstanding modern progress has enabled us to suspect even the most obscure case of cancer by the cachectic look, that indescribable appearance of the face with which the formidable disease seems almost invariably to stamp its seal upon the features of the doomed individual; by the rapid wasting of all the tissues of the body, caused by the poisoned blood, which has become unfit to sustain the mysterious process of assimilation; by the more or less sharp or dull, but nearly always constant, pain; by the frequent appearance of a tumor at the seat of the cancer; and by the special symptoms of each individual case, depending upon the locality of the malignant growth; and notwithstanding we may ameliorate the suffering of the patient, it is questionable if, in cases where surgical interference is impossible, the most careful treatment does ever prolong life one solitary minute.

Can it cause wonder, therefore, that every human being dreads this fearful malady, which so certainly ends life within a short period after it has once made its unmistakable appearance? Can we be astonished that even physicians take up with haste every new remedy which is brought, by some accident or through a selfish motive, into public notice as a "sure cure" for cancer? Only a few years ago the whole civilized world turned its eye toward Brazil; the representatives of every nation in that country received letters of inquiry and orders by the thousands; everybody wished to know the truth as regarded the effect of *condurango* on cancer. and the laity, as well as the medical profession, all wanted a "genuine" specimen of it. It became the grave object of diplomatic intercourse; hundreds of articles were published in medical journals, and appeared in secular papers *pro et contra;* and even so high an authority as Professor Frerichs, in Berlin, contended that he had cured an undoubted case of malignant thickening and narrowing of the pyloric orifice with the celebrated remedy;* and now, only a few years later, the commission appointed to revise the new pharmacopœia of the German empire, a commission composed of the highest authorities in the science they represent, has rejected condurango,† which will soon be added to the great mass of obsolete articles of our materia medica.

And now appears a new remedy, or rather a substance known for many years, but never recommended for the purpose it now is. It comes to us from England, heralded as a "sure" means for curing cancer: *Chian Turpentine.* And, again, we have a reputable physician, occupying a responsible position, Prof. John Clay, obstetric surgeon to the Queen's Hospital, in Birmingham, who, basing his opinion upon a number of observations, considers Chian turpentine a "sure cure" for cancer, also recommends it especially for cancer of the stomach, and remarks that it is advisable not to be too precipitate in rejecting a case of uterine cancer on the ground of its being too far advanced for treatment,‡ and cites a case "to the point," in which a woman, who was almost dying, improved so much after a nine weeks' treatment by Chian turpentine, that she was about leaving the hospital with "every prospect of soon being cured."§

When I read this article (about three months ago) of Prof. Clay, I had under treatment one cancer of the uterus and one of the liver and stomach, both of which I immediately put on Chian turpentine. Another case of uterine can-

* As in the cases in which Billroth removed the larynx, and only lately the stomach. *Vide* article, "A Second Resection of a Part of the Stomach, by Billroth." *International Jour. of Med. and Surg.*, March 29th, 1881, p. 295.

* Frerichs published this case, during the height of the "condurango boom," in the *Berliner Klinische Wochenschrift*, but I have not been able to find the number again.

† Medical and Surgical Reporter, March 26th, 1881, p. 356 *et seq.*

‡ New York *Med. Abstract*, January, 1881: abstract from an article by Prof. Clay, which appeared in the London *Lancet*, December, 1880.

§ Loc. citat.

cer was soon after handed over to me for this special treatment, by the physician in charge of the out-clinic of a large hospital here, and through the kindness of two brother physicians, two more cases were given into my charge, both of which were cancer of the pyloric orifice of the stomach.

Before speaking of Chian turpentine itself, its pharmaceutical history, mode of administration, and its effect in cancer, I will give a history of these five cases, as much condensed as consistent with my purpose.

Case 1.—I. H., forty-nine years old, was visited by me the first time December 5th, 1880. She gave me her history as follows: Never had any serious illness; was delivered of eight children, of which the youngest was then seven years old; and her menses had always been regular, except when enceinte or nursing a baby. About six months ago they seemed to make their appearance oftener, to last longer and to increase greatly in quantity each time. But even before this change happened, she felt as if something was wrong with her womb, as she had frequently recurring sharp pains, of which she formerly never suffered. A fetid acrid discharge had also appeared, her appetite was "non est," and she wasted to a mere skeleton. Her urine seemed of late to come from the vagina, and the discharge from the latter had now a fecal odor. The examination revealed a carcinoma, which occupied the whole neck and part of the body of the womb, the whole cul de sac, the bladder and the rectum. The whole was hard and contracted together into one mass, and from a large ulcer, which had eaten away nearly the whole vaginal portion, occurred a severe hemorrhage the moment I touched it. The discharge was remarkably offensive. As regards pain, sleepless nights, difficult and painful evacuation of the bowels, and the other symptoms of such a pitiful case, they were all present. Being fully convinced that all surgical interference came here too late, I directed my whole attention to ameliorating her miserable condition. I regulated the diet, gave her an anti-dyspeptic mixture* and pepsin, ordered tonics† and a dose of morphia at night, and applied Monsell's solution to the affected parts, keeping them a longer time in contact with it by the aid of a tampon, which application was occasionally repeated. I also prescribed a disinfecting wash, and had the pleasure of making my patient feel quite comfortable after about two weeks of this treatment. Her appetite was improved, most dyspeptic symptoms had left her, the hemorrhage as well as the so very offensive odor of the discharge had ceased, and the parts presented a much cleaner aspect. In this relatively comfortable condition she continued till January 22d, of this year, when I, without interrupting the treatment just mentioned, gave her the Chian turpentine, as will be further described hereafter. Without any change in the symptoms whatever she lived till February 19th, a.c., when she died. There was not the slightest impression discernible, either local or general, which could have been ascribed to the turpentine. The cause of death was sheer exhaustion.

Case 2.—N. G., 64 years old, came under my charge December 17th, 1880. He had the cachectic appearance and fawn yellow color of cancer, and was evidently very much emaciated. He gave me the usual history of cancer of the stomach—vomiting, sour eructations, pain, etc.—and complained especially of a severe pain in the right hypochondrium. On examination I detected a hard, round, uneven tumor, occupying the region of the pyloric orifice of the stomach, which latter was greatly dilated. To the right of this tumor, a little lower down, was a smaller new growth of the same kind; the liver was greatly increased in size, very sensitive to the touch, and very uneven, especially at its margin, and over the liver near the stomach existed a good-sized patch, of about two inches in diameter, of local peritonitis. Here the patient could not bear the slightest pressure. I ordered the application of a large (four by six inches) emplastrum cantharidis directly over the seat of the peritonitis, to be followed by a healing salve,* and this again by an emplastrum conii as soon as the skin was in its normal condition. I then regulated the diet as follows: He should take one tablespoonful of good, pure milk (unboiled, hot, warm or cold) with lime water added (f. ℥j to Oj), every half hour; every other hour to take in place of the milk about one and a half drachms of finely-scraped raw beef (tenderloin);

*℞ Sodii bicarbonatis, ℥ss
Tincturæ nucis vomicæ, f.℥j
Tincturæ gentian. comp., f.℥iv. M.

Sig.—f.℥ij t.d. in half a tumblerful of water one hour before each meal.

†℞ Elix. cinchon. calisay.,
Elix. cinchon. ferrat., aa f.℥iv. M.

Sig.—f.℥ss t. d., diluted with the same quantity of water one hour and a half after meals.

* An ointment which with remarkable rapidity heals the sore caused by a blister:—

℞ Unguent. zinci benzoat., ℥ij
Acidi carbolici, gr. iv
Balsam. Peruviani, f.℥iij. M.

Tere quam subtilissime ut fiat ungt.

Sig.—Externally, ter die.

every fourth hour to add to the milk half a drachm of Johnson's fluid beef, and to have three times daily—morning, noon, and night—instead of the milk, the following: one tablespoonful of barley gruel (made with water, and put through a sieve), half a teaspoonful of powdered stale bread, and half of a soft boiled egg, to be followed by ten grains of Boudeaul's pepsin, which, I will here remark, is so superior to any other pepsin, that no testimony, by whatsoever authority, will ever induce me to use any other pepsin again. I further prescribed a cathartic pill,* to be taken at night whenever there had been no motion of the bowels during the day. The effect of this treatment was magical. From that day the pain almost entirely disappeared, never returning with any degree of severity; all vomiting and sour eructations ceased, and the patient actually gained two pounds in weight within the next three weeks. But he then gradually commenced to lose again, although comparatively continuing to suffer very little, as none of the former symptoms returned, except a slight, dull pain, which never totally left him, but did not seem to annoy him much. January 22d I put him on Chian turpentine, and kept up that treatment until February 14th, when he died of exhaustion. The turpentine had no effect whatsoever, either on the size or hardness and shape of the tumor over the stomach, or on the size and irregular outline of the liver, or on any general or local symptom or sign.

Case 3.—B. McC., 52 years old, complained of lancinating pain in the lower part of her abdomen, a fetid discharge from the vagina, hemorrhages, want of appetite and gradual loss of strength and flesh. The neck of the uterus was very hard and uneven, and a corroding, ugly looking ulcer, which bled at the slightest touch, occupied the whole lower and a small segment of the upper lip. She was handed over to me for treatment February 12th. The same day I commenced to give her Chian turpentine, and continued to do so till March 27th, when, not having improved in the least, but, on the contrary, having steadily become worse, she left me, in utter disgust with the treatment. I now regret that I lost over six weeks in such an utterly useless manner, when surgical interference in the beginning might have prolonged or even saved her life. The ulcer had greatly increased in size, occupying the whole neck, and the hardness had extended up to the body of the uterus and the left broad ligament, involving the left ovary and surrounding parts.

Cases 4 and 5.—P. McI., 59, and Ch. S., 71 years old, were given in my charge January 25th and January 28th, respectively. The history of both patients was similar. They had been rapidly losing strength and flesh for some months past, and complained of vomiting and of pain in the epigastric region, where both exhibited a hard, uneven tumor. The only difference between them, as regards their pathological condition, was the fact that McI. would vomit a few hours after every meal, and S. only every night, when his stomach would eject nearly all the food the poor fellow had eaten during the day, in a state of highly acid fermentation. I put them both on Chian turpentine, *without interfering with their usual diet or giving them any other directions or remedies.* March 14th, after I had, therefore, continued this treatment for the full period of six weeks, they were not only not improved in the least, but rapidly getting worse, both, especially S., becoming fearfully emaciated. In both, the tumors had decidedly increased in size and hardness, and the dilatation of the stomach become enormous, more so in S., who had, on several occasions during the last week, vomited large masses looking like coffee grounds, indicating hemorrhage from the stomach. It was only with the greatest difficulty that I persuaded them to continue the treatment, and my promise alone. that I would stop it after six weeks, when the benefit (?) would become apparent, caused them to continue with me. As regards S., I was afraid he would not live long enough to see if I kept my promise, but being bent on giving the Chian turpentine a fair trial, I carried out the treatment. On the day mentioned, March 14th, I discontinued the turpentine, and put them on exactly the same treatment which I described somewhat at length in the case of N. G. A decided improvement began at once. Vomiting and the sour eructations ceased, and the occasional application of leeches, or of a blister and of a conium plaster, made them comfortable as regards the pain in the epigastric region. They both assured me that they were now convinced of the effect of the former (Chian turpentine) treatment, and of their eventually getting well, never dreaming to what cause the change in their condition actually was due. Poor S., though, did not enjoy the respite

* This pill is certain in its effect, causing no griping, and is especially of value in cases of disturbed portal circulation. hemorrhoids, etc.:—

Ut fiat pilula.

Sig.—Take at night, when necessary.

long; he died on April 2d. McI., who, before this dreadful malady affected him, must have been a remarkably strong man, is still holding out and following my directions to the very letter, and is, as far as symptoms are concerned, unconscious of the doom which must inevitably be very soon his also.

The foregoing are not "picked" cases, but were taken as I could get them. As only several and very high, trustworthy authorities could make me believe in any remedy, as being a "sure cure" for cancer, I never would, perhaps, have paid any attention to this Chian turpentine treatment, had I not had accidentally on my list two cases of cancer, when first reading Prof. Clay's article thereon. Though, before I draw any conclusions* from the cases given above, I wish to make a few remarks as regards the remedy itself.

Having read only lately, that no genuine Chian turpentine was in the market,† I will give a description of the article which Prof. Clay himself‡ considers to be the genuine turpentine.

Genuine Chian turpentine has a fragrant, well marked odor, which becomes readily perceptible when rubbing a small portion between two fingers. It must not have a strong odor of pine wood, should possess a pale amber color, and be free from impurities; if whiter, and resembling glazier's putty, it has been well washed with water, to free it from impurities, and water can be easily forced out of it, if a portion is subjected to pressure between two pieces of glass. Its taste should be mildly terebinthinate and readily disappear again. If, at first, it seems tasteless and then assumes a bitter, nauseous flavor, causing eventually a strong, sickening sensation at the back of the throat, and adheres to the fingers, it may be turpentine gathered in Cyprus, but not Chian turpentine. Lastly, if a small portion of the genuine drug be placed on a piece of glass, and exposed to the atmosphere, it thickens considerably after this exposure. Should such evaporation not take place, the article is spurious.

We will see, now, what that standard and most reliable work—completer and fuller of information than which no language possesses one—the "Dispensatory of the United States," by Wood and Bache, has to say on that subject.* I can only give a very short abstract from it.

"Chian Turpentine is collected by incisions made during the summer in the bark of pistacis terebinthus, chiefly in the Islands of Cyprus and Chio, the latter of which gave it its name. It is, if unadulterated, a thick, tenacious fluid, of light greenish-yellow color, has a penetrating but more agreeable odor than other turpentines, and a mild taste without bitterness. On exposure to air it speedily thickens. As each tree gives only a small quantity, the Chian turpentine commands a high price even in the place where it is procured. Very little of it reaches this country."

My apothecary procured me Chian turpentine from one New York and two Philadelphia firms. Two of the specimens were evidently spurious, but the third coincided so exactly with the descriptions of the genuine given above, that there could be no doubt of its being Chian turpentine. The drachm of it was sold for ninety cents. I believe that as soon as the wholesale druggists become convinced that no "Chian turpentine boom" can be expected in this country, the price will fall down to about three dollars per ounce, which seems to me to represent somewhat nearer the commercial value of the article. How much the late earthquake in Chio may influence the market I cannot guess.

Prof. Clay lays the greatest stress on the mode of administering the remedy. This fact alone should have made me somewhat suspicious, as Chian turpentine, if really a sure cure for cancer, will act, no matter how, if only given *secundum lege artis*.† The best mode of prescribing it is in pill form‡ or in emulsion,§ the dose for an adult being three grains, increased gradually to five.

Now as regards the conclusions that may be drawn from the above mentioned cases: I premise that whenever the effect of a new remedy is to be tried, it is necessary to give to the patient nothing else whatever which by itself may influence the malady, if the results obtained shall be reliable. We should further

* My conclusions coincide fully with those arrived at by Henry Morris, M.A., M.B. (New York *Med. Abstr.*, March, 1881, p. 90: abstract from article in London *Lancet*, February.) When my article had been written, I asked the Editor of the Med. and Surg. Rep., Dr. D. G. Brinton, for the January number of the New York *Med. Abstr.* (containing abstract of Prof. Clay's article, as I had mislaid it, and Dr. Brinton sent me at the same time, Mr. Morris' article, which I then saw for the first time (about April 1st).

† *The American Specialist*, April, 1881, page 63, *et seq.*

‡ Loc. citat.

* Twelfth edition, 1868, pp. 831 and 833.

† Did Liebreich give explicit directions, how to prescribe chloral, when he recommended it as a most certain hypnotic? He only advised us as regards the medium dose.

‡ ℞. Terebinthinæ Chianens, grs. lxxij usque ad cxx.

not forget, as Mr. Morris correctly remarks*, that cancer often comes to an apparent standstill for a longer or shorter time.† As regards the length of time I put my patients under the Chian turpentine treatment, I considered four to six weeks fully sufficient to test the merit of the remedy, as Prof. Clay has found during the same period a decided improvement in his patients. Examining now my cases, the following conclusions must be arrived at.

If Chian turpentine is administered alone, and no further directions are given as to diet, disinfecting, symptomatic treatment, etc., it shows not the slightest effect whatever, neither on the local disease nor on the general cachexia, and the cases rapidly get worse.

If all possible means are taken to remove everything which might irritate the malignant growth, increase the severity of the symptoms, and favor the dangerous consequences of the cancer (as, for instance, overloading of the stomach in cases of cancer of the pylorus, thereby causing dilatation of the organ, highly acid fermentation and earlier ulceration of the new growth), if symptomatic treatment is carried out as far as is in our power, we are able to make life bearable at least, and to remove many, if not, as in some cases, almost all annoying symptoms. If Chian turpentine be now given, after the patient has received the benefit of the treatment just mentioned, and while continuing the latter, the apparent improvement goes on, but the turpentine has here again no further influence whatsoever.

If Chian turpentine is given at the same time when the treatment is adopted, of which experience has shown us that it will ameliorate the case and remove many, or lessen the degree of severity of many symptoms, the cases will immediately take on a different aspect, and will apparently improve, but not more so than if the latter treatment alone had been instituted, without any Chian turpentine.

Chian turpentine influences, therefore, the local and general symptoms of any case of cancer less than a symptomatic treatment, based upon a correct knowledge of the case and of its evil tendencies; nay, it has, given alone, no influence whatsoever, and is utterly useless, producing not the slightest effect.

Where surgical interference is impossible we can only try to ameliorate the condition of the patient, who is doomed to die. This is a testimonium paupertatis, but the truth; and at present we can only console ourselves with the old Roman adage: Ut desint vires, tamen est laudanda voluntas. But if any new remedy is again brought forward as a "sure cure" for cancer, a remedy which would be a present of the greatest value to suffering humanity, we had better remember the words: Quidquid id est, timeo Danaos, et dona ferentes; and never forget: Quidquid agis, prudenter agas et respice finem.

812 *N. Fifth street, Philadelphia.*

* Loc. citat.

† As for instance in pregnant women, affected with cancer. During pregnancy the cancerous growth will, in most cases, not further develop itself; the cachectic and other symptoms will mostly cease; but, pregnancy being over, the progress of the case will now be the more rapid.

SURGERY, AS PRACTICED BY THE INDIANS.

BY H. M. M'CLANAHAN, M.D.,
Of Montana.

This branch is not enveloped in a cloud of mystery and superstition, as is the practice of medicine, although far from being free from it. The reason is obvious. The causes of disease are not always manifest, even to the most cultivated, while to the Indian it is entirely a subject of speculation. However, the relations between cause and effect, in many surgical injuries, are so evident as to convince the most ignorant. But self evident as the cause frequently is, the Indian is not satisfied with that alone, but goes further and seeks for a first cause to account for the accident, and here the influence of spirits is admitted. Some higher power must have influenced the horse to fall, or the bullet to strike him. Holding such beliefs, it will not seem strange that the Indian, before going to war, or to hunt, should endeavor to prevent accidents. This he does by "making medicine" before commencing the journey. Now, "making medicine" is a comprehensive term, and may mean songs, dances, supplications, or the wearing of charms. Before starting, the Indians will make dances, and sing songs to the gods, and wear about the body pieces of cloth, skins, etc., as charms. Thus equipped, he is ready for war or the chase. He now pretends to believe that no harm can come to him. I believe this is the reason why the Indian, at times, displays such courage, for naturally he is a coward. If, as often happens, the charmed Indian is injured, he does not lose faith in the charm, but explains it away by asserting that either his medicine was not strong enough, or the enemy's was stronger.

If a wound takes on morbid action it is attributed to evil spirits.

Further views as to their ideas of cause will be given as various orders are taken up.

First, the treatment of wounds, however caused, involving injury to or destruction of tissue. There are certain general principles of treatment which are generally recognized, among which may be recognized arrest of hemorrhage, removal of foreign bodies, and protection of the injured part by coverings.

For arresting hemorrhage they simply apply compresses over the seat of the injury. A favorite application is the spider's web, applied intact. The blood, becoming entangled in the meshes, clots. In urgent cases, anything, as grass, dried leaves, and the inner bark, or pieces of blankets, is used. The Indian is aware that violent hemorrhage, uncontrolled, means death.

The primary dressing is left in place until removed by ulcerative action. Then the wound is examined, and any foreign bodies, as shreds of cloth, pieces of wood or earth, are removed. In rifle wounds the ball is not disturbed, unless in sight. They are not inclined to meddle, confining attention to the surface. As an application, marrowfat is probably most frequently used. Another favorite ointment is the fat of the prairie dog. In washing the wound, cold water is used. General or local fever is considered as evidence of the intervention of evil spirits, and not as a necessary result of the local lesion. In such cases the "medicine man" exerts his powers to dispel the evil genii. His manner of conducting the scaring process was described in the preceding article. The procedure would be the same in this instance. They have no fixed times for changing the dressings; as a rule, so long as the patients are comfortable the wounds are not molested.

Complications, as erysipelas, gangrene, and pyæmia are very rare. I have never seen such complications. Medicine men, however, tell me of cases where the flesh turned black. They said that in such cases the patients invariably died. When asked the reason, the reply was, "too strong for our medicine."

While a digression, the following facts may be of interest: The air of the lodge is charged with wood smoke, from the open fire on the ground. There is free interchange of air. Meat hanging in the lodge is perfectly preserved at all seasons. I have thought the absence of the complications alluded to might, in part, be due to the antiseptic properties of the smoke. In punctured wounds the medicine man sometimes desires to introduce substances into the wound. For this purpose he procures the wing bone of the wild goose and removes the marrow. To one end of this is attached a piece of small intestine. The bone is then introduced into the wound, and the medicine into the intestine. Then, by drawing it between the fingers, the substance is forced through the bone into the cavity of the wound. Such is an outline of the Indian's manner of treating wounds.

We next proceed to give the treatment of fractures and dislocations. Most of the accidents of this class occur during the chase of buffalo. In civilized life many fractures are due to falls. Such causes almost never occur among the Indians. They wear moccasins, which have flat soles, and do not cramp the feet. The moccasin is made of rawhide, and does not become smooth, as does tanned leather. In compound fractures the treatment is more elaborate than in simple fractures.

The following is the treatment for that form: First, reduction by extension and counter extension. Some of the Medicine men acquire considerable skill in manipulation, and their results are creditable. Next, all the openings are filled with extracts. Then, over all, is smeared a coating of the scrapings of rawhide boiled in water. This forms a gelatinous layer, having considerable force. Over this and around the entire limb is placed a covering of fine inner bark; the limb is then ready for the splints. The splints are made from willow or other wood, quite thin, and from one to two inches in width, and made long enough to extend the entire length of the bone. They are placed about one inch apart, and entirely around the limb, being held in place by circular strips of cloth. If it be an arm, it is carried across the chest and retained by a circular bandage about the neck. If a leg, the patient remains in the recumbent posture for some days; but not during the entire time of the healing process. The rule is for the patient to commence to walk as soon as he can bear the weight of the body upon it without causing pain.

In simple fractures the treatment is not so elaborate. The splints are applied next the skin, in the same manner as in compound fractures. The original dressings are not changed unless, from swelling, the arm becomes painful. In comminuted fractures the limb is dressed as in compound fractures. When spiculæ of bone, thrown off by the efforts of nature, appear on the surface, they are drawn away, but are not searched for. I have never heard of the Medicine Man performing an amputation, and in severe comminuted fractures death often results.

In dislocations the treatment is similar to that in fractures. From what I have seen, I judge

the reduction is often imperfectly accomplished. The joint being bound up in splints until pain has ceased, the result is frequently a stiff joint. I saw a case, where the middle finger had been dislocated backward upon the dorsal surface of the articulating metacarpal bone. It had not been replaced, and the result was an artificial joint, allowing of considerable motion. The head of the metacarpal bone was partly absorbed, so that the contour of the joint was not greatly changed. The finger *appeared* much shorter than natural.

In common with all other races of man, the Indian suffers from venereal diseases. He is aware of the existence of such diseases. He is ignorant of the fact that secondary and tertiary forms are the result of the primary disease. They are looked upon as distinct diseases. The following dialogue will illustrate his ideas of cause. The victim is suffering from gonorrhœa:—

When did you get this? "Last week." Did the woman have any disease? "No." How did you get it then? "She made bad medicine, so as to give it to me." The victim was very indignant to think she would play such a mean game on him.

This idea that a woman can give a man the clap at will, is the cause of frequent domestic disturbances.

The treatment consists in taking, internally, a balsam that is collected from the wild cherry and other trees. They use no injections. What the result in these cases is, in many cases, I do not know, but I have never seen a case of stricture, and have never known of one to suffer from retention of urine.

For syphilis I have never been able to learn of any treatment. As before remarked, it is not recognized as a distinct disease, and its manifestations would be treated as distinct lesions. As a clinical fact worthy of notice, I can say, as the result of my observation, that syphilis does not make the terrible ravages as among civilized people. Inherited syphilis is more marked than acquired.

Counter-irritation is a favorite form of treatment for many ills.

The instrument employed is a piece of flint drawn to a sharp edge. The skin is scored until blood exudes freely. This treatment is employed for all swellings and tumors, and any deep seated pains. For painful forms of ophthalmia scoring the temple is frequently employed. But it is while mourning that this practice is most universally employed. I saw one woman whose entire body was lacerated in this way, so that she left blood-stained marks in every impress of her feet.

In incontinence of urine the treatment generally is the sweat house, but sometimes the Medicine Man will attempt to draw off the urine, using for this purpose a quill. It is not passed into the bladder but only part way along the urethra. It often happens that there is a free flow of blood following this procedure.

Considering the severe winters in this latitude, it is surprising how few suffer from frostbite. Most Indians paint the face with vermilion, daubing it on thickly, which, I think, protects it from the cold somewhat. Then they very seldom apply water to the surface of the body in winter. To protect the feet, fine dry grass is placed inside the moccasin, which produces friction, thus maintaining the heat of the part.

Such is an outline of the Indian's idea of the practice of surgery. Experience has taught him a few facts, but I doubt if he is any wiser than his ancestors were in the year 1492. If he should live for ages to come uninfluenced by the whites, he would know no more than he does now.

Hospital Reports.

PHILADELPHIA DISPENSARY FOR SKIN DISEASES, AND SPECIAL CLINIC FOR SKIN DISEASES AT THE NORTHERN DISPENSARY.

An Analysis of Six Hundred and Fifty-three Cases, With Remarks on Treatment.

By H. W. Stelwagon, M.D., Physician in Charge.

During the year 1880 six hundred and fifty-three patients were registered. In this number were observed fifty distinct diseases.

In the accompanying table only those affections of which four or more cases were noted are mentioned, representing six hundred and fourteen patients. In the remaining number, thirty-nine, were three cases each of herpes, simple erythema, vitiligo and condyloma; two cases each of epithelioma, lichen planus, comedo, herpes iris, scrofuloderma, atrophy of the nails and ecthyma; one each of morphœa, dysidrosis, milium, lupus vulgaris, lupus erythematosus, alopecia areata, hypertrophy of the nails, sycosis parasitica, lichen pilaris, pernio, zanthoma, sebaceous tumor and alopecia simplex.

The first twelve diseases tabulated are representative of five hundred cases, more than seventy-five per cent.

Eczema, by far the most common of all, occurred in thirty per cent. of all the cases.

This disease was seen in one-third of the cases in those under the age of fifteen. Males and females were equally affected.

Old chronic eczema rubrum of the legs was very frequently encountered. The papular form was also quite common, as was likewise the im-

petiginous variety, this last chiefly in young children. In the majority of cases the general health seemed unimpaired.

The almost constant co-existence of digestive derangement, however, particularly of constipation, was recorded. In a number of instances a hereditary tendency was disclosed.

The *syphilodermata* were seen in over ten per cent. of the cases. The papular form predominated; and in this the papulo-squamous, the so-called psoriasis syphilitica, was largely represented. The almost identical appearance of this eruption with the patches of simple psoriasis was, in some cases, remarkably striking. In the several cases of the tubercular syphiloderm there existed but one or two patches; and in these the tubercles were arranged in a peculiar, circinate manner, the patch originally beginning as a ringed group and gradually extending at the periphery by the accession of new tubercles, the centre in the meanwhile becoming free from the eruption, leaving, however, a slightly pigmented condition of the skin. This form, in which there was no tendency whatever to ulceration, was seen in but two instances.

The circinate, serpiginous form, in which *ulceration* attended, was not so infrequent. In these localized tubercular eruptions, the similarity to lupus vulgaris, as was shown in the cases referred to, was very great. The long duration and slow progress frequently observed in this syphiloderm, when uncared for or inefficiently treated, was exemplified by one of the few cases which came under observation. The pustular eruption was seen in four instances, and in each there was and had been considerable impoverishment of the general health. There was also in these four cases marked glandular enlargement, and in two, iritis had supervened.

Urticaria was noted in six per cent. of the cases; in more than half as an acute affection. Of the chronic cases, the greater number were in children, in those under the age of fifteen, and in the papular form—urticaria papulosa. The presence of dyspeptic symptoms was frequently noticed. The affection seemed to have a predilection for those of a nervous temperament.

A large number of the cases of *dermatitis* resulted from exposure to the poison ivy. The effects produced varied from the simple erythema to the severe bullous inflammation. In the latter cases there was slight constitutional disturbance.

Pruritus cutanea was observed in over three and a half per cent. of the patients. In nearly all, the patients had passed the fortieth year; four-fifths the fiftieth. In several of the severe cases Bright's disease was observed to coexist. The existence of diabetes was not noticed. Two-thirds of the cases occurred in males. In several the disease was limited to the parts about the genitals.

Psoriasis was observed in the same proportion as pruritus; that is, in three and seven-tenths per cent. The eruption was, as a rule, general; two cases noted, however, in which the scalp alone was diseased. The extensor surfaces of the elbows and knees were in a large percentage primarily affected, but not so large a number as to be corroborative of the great stress usually laid upon this point. In one of the cases the subject was a child under four years. The disease had already existed a year, and presented the same general aspect as in the others, probably less inflammatory. The eruption was typical of the variety known as psoriasis guttata, except on the extensor surfaces of the elbows, where the patches were confluent.

As many as twenty-one cases of *impetigo contagiosa* came under treatment. All were seen at the Northern Dispensary. The disease, as was subsequently learned, seemed to be confined to the northeastern section of the city, where it prevailed to a great extent.

Herpes zoster was observed in sixteen instances—two and four-tenths per cent. The eruption was most frequently seated upon the thoracic and lumbar regions. The right and left sides about equally. In but few of the cases was pain a very prominent symptom. In more than half there was no acknowledgment of premonitory neuralgia elicited. Neuralgia of the parts was frequently complained of in the course of the disease, but was of moderate character. A poor condition of health was remarked in nearly all.

Furunculosis was recorded in a little more than two per cent. of the cases. In nearly every instance a broken down condition of the system existed. Even those whose appearance was indicative of a fair standard of health, upon inquiry, admitted a previous reduction in the health forces. The upper region of the body seemed preferred.

In the cases of *erythema multiforme*, the papular form of the eruption predominated. Except one case, which was observed in winter, they all came under treatment during spring and fall, and all in those under the age of fifteen. In two cases were noted pain and swelling of some of the joints, but in both, these symptoms proved of short duration and trifling import. This affection occurred in the proportion of two per cent.

Twelve cases of simple *impetigo* were noticed. In none, so far as could be ascertained, had the pustules been produced by any local irritants, such as pediculi, or other vermin. Almost all the patients with this affection came under treatment during early fall. General condition was noted to be below par.

But few of the remaining diseases call for special remarks in a general analysis of this character.

Rosacea was seen in its milder forms in ten cases, chiefly in unmarried women, usually suffering from some uterine disease.

In two (brothers) of the cases of *favus*, the scalp was the part affected, and almost in its entirety. The disease had already existed for several years. The hairs were dull, split, and broken off, and in places were bald atrophic areas, giving the head a peculiar, scarred appearance.

In the remaining two cases the disease was seated on other parts. In each of these latter, the characteristic yellow cup-shaped discs were beautifully shown.

In one of the nine cases of *tinea versicolor* the

disease extended down the abdomen as far as the pubes, and down the arms to several inches below the elbow.

Hyperidrosis was recorded in four instances, in all of which the affection was limited to the feet, and especially the soles. In all, the occupation of the patient was such as required constant standing.

But two cases of *epithelioma* were treated. These were of a superficial character. Both patients had passed middle life. There were no subjective symptoms.

Two cases of *lichen planus* were recorded. The flexor surfaces of the wrists and forearms were the parts on which the eruption was seated. The disease was symmetrical, and had existed many months. The square, flat, purplish, glazed and irregularly grouped papules were characteristic. The general health appeared normal.

In one of the two patients with *herpes iris*, the eruption was most beautifully exhibited. The arms, legs, and trunk were, to a great extent, covered with the rainbow-colored patches, each consisting of several concentric rings. The vesicles were small and abortive. The last vestige of the eruption disappeared at the end of three months.

Of the remarks on *treatment* following, it is not intended that they should be much more than general in character. Of the use of new remedies but little will be said, as such, when occasion warrants, will be otherwise communicated. Treatment of skin diseases, as practiced at dispensaries, must, of necessity, if expected to be carried out, be the simplest possible. Also, as regards the matter of economy, there must be some consideration in prescribing. Yet, with these disadvantages, the results in the cases reported were gratifying. The success, in many cases, was not so much due to the particular medicine, lotion or ointment used, as it was to the fact that in every case minute directions regarding the mode of application and the necessity of persevering attention to the same were given.

In the cases of *eczema* in which there was considerable accompanying inflammation, diachylon ointment proved of the greatest service. Oxide of zinc ointment, with an equal part of cosmoline, was found also very soothing. In the less inflammatory cases, white precipitate ointment, of varying strength, was advantageously employed. In the dry, scaly forms, the preparations of tar were relied upon. The fact that tar disagrees with some skins should not be lost sight of. In old cases of eczema rubrum of the leg, the rubber bandage was ordered, when the patient could afford it, and with the greatest advantage. In not a few cases the use of this bandage, with an occasional washing of the parts with a weak solution of carbolic acid was followed by rapid improvement, and eventually by full relief. In place of the carbolic acid solution, a lotion of salicylic acid was often employed, and apparently with about the same benefit. In the papular forms of the disease, oil of cade, in alcoholic solution, and also a wash of carbolic acid, were used with some success. In all cases an endeavor was made to ascertain the predisposing cause, and if any could be detected, the constitutional treatment was directed against the faulty condition discovered. Arsenic was found most useful in the chronic scaly disease. In children the continued administration of cod-liver oil appeared to be of considerable benefit, and a small dose of calomel was ordered about every second or third day. In adults an aperient tonic mixture gave good results.

In the *syphilodermata*, no local treatment was employed, except in the tubercular and ulcerating forms. In these the constant application, in the form of a plaster, of mercurial ointment of about half strength, aided materially in effecting a disappearance of the eruption. In the early secondary eruptions the protiodide of mercury was given. In the late syphilodermata a combination of corrosive chloride with iodide of potash proved of most value.

In *urticaria*, in acute attacks, especially where digestive disorders seemed to be the cause, antacids and laxatives were prescribed. In those chronic and troublesome cases of the disease, quinine, in tolerably large doses, was of the most value. Atropia was given with fair results, but quinine seemed more certain. In those cases also, where there were dyspeptic symptoms, muriatic acid and pepsine were ordered.

In *non parasitic sycosis*, the application of diachylon ointment and daily shaving were followed by rapid improvement. After a certain point was reached, however, the affection was not so responsive. Stronger applications were then made, and epilation practiced.

In *phtheiriasis* of the *scalp*, simple petroleum was ordinarily used, and with good results; care was taken to protect the neck and face.

In *phtheiriasis* of the *body*, thorough cleansing of the clothes and person, when practicable, was the quickest and most satisfactory method.

In *dermatitis*, from rhus poison, the simplest, and about as efficient as any application, was lead water. A weak solution of carbolic acid was also of use.

In *pruritus*, if any faulty condition of the system existed, the same was corrected. Some benefit, in several cases, was derived from large doses of bromide of potash. Local applications of the various antipruritic lotions were made, with varying results. Probably, carbolic acid in proper solution was the best.

In the local treatment of *psoriasis*, reliance was placed in three remedies: chrysophanic acid, pyrogallic acid, and oil of cade. Each was applied in the form of an ointment of the strength of from a half to one drachm to the ounce of adipis or simple cerate: oil of cade often in greater quantity. Chrysophanic acid was quickest in its results, but on account of the severe inflammation of the skin it sometimes causes, the least generally applicable. Pyrogallic acid was probably most used. The removal of the scales was best effected with sapo viridis.

In proper cases, arsenic was given with decided advantage; especially useful in the older and less inflammatory symptoms. Where there was constitutional impairment, cod-liver oil and iron were given.

In the cases of *acne*, various plans of treatment were tried. In scrofulous patients, cod-liver oil

was of essential service. In the more inflammatory acne, great benefit was derived from small doses of Epsom salts, taken well diluted, once or twice daily, before meal time. Where dyspepsia existed appropriate remedies were given. Of the local applications, the best were an ointment, or lotion of sulphur, and a lotion of corrosive sublimate. In the indurated form, local scarifications were decidedly curative. In all cases where comedones existed the same were ordered to be pressed out. Nightly washing of the *face* with hot water was of some advantage.

Herpes zoster was treated on general principles: local application, merely for protection, and quinine internally. Phosphide of zinc was given in a number of cases, but not enough to warrant an expression regarding its value. Where there was coexistent neuralgia, morphia and atropia were ordered.

In the treatment of *furunculosis*, sulphide of calcium was given, but without the success so urgently claimed for it. It is possible that the cases were not suitable, but even in those where there was no apparent disturbance of the natural vigor, after a fair trial the remedy was discarded. Fowler's solution, with large doses of tr. ferri chlorid , was prescribed with greatest confidence.

But few of the remaining diseases need to be noticed, in regard to treatment pursued.

In *scabies* an ointment composed of about a drachm each of washed sulphur, balsam of Peru, glycerine, to the ounce of lard or simple cerate, was successfully used.

In *rosacea* stimulating lotions and ointments seemed of value. At the same time the necessary constitutional treatment was ordered. The disease frequently improved upon treatment directed toward strengthening the digestive power. Where there was existing uterine disease, the same was ordered to be treated, and generally with improvement of the rosacea.

In *tinea tonsurans* and *tinea favosa*, chrysophanic acid appeared of some advantage, but unavailable on account of the unsightly staining it causes.

Carbolic acid, in varying proportion with olive oil, as high as equal parts, was of greatest value. Epilation was essential in cases where the disease had existed any length of time. Frequent washing of the whole scalp with a weak solution of carbolic acid was found of the utmost service in preventing the disease from spreading.

In the four cases of *hyperidrosis* of the feet, an ointment of tannic acid, applied in the same manner as was advised by Hebra in the use of diachylon ointment, was followed by success.

In the cases of *epithelioma*, an ointment of pyrogallic acid (℥j–℥j) was applied as a plaster, and proved curative.

As already remarked, in all cases of the various diseases coming under notice, the necessity of thorough application was emphasized, and where treatment was persisted in, the results were satisfactory.

An interesting observation was made regarding the frequency of different diseases as seen at the *special* Dispensary and at the *general* Dispensary. An analysis based upon the cases seen at one dispensary would be entirely different from that based on those observed at the other. When a sufficient number of cases shall have been recorded at each Dispensary, a comparative analysis will be made and the results communicated.

	Whole number of cases.	Under the age of 15 years.	Over the age of 15 years.

Tracheotomy Without Tubes.

Dr. Alfred C. Post, of New York, writes, in the *Annals of Anatomy and Surgery* :—

My personal experience in tracheotomy without tubes, according to the method suggested by Dr. H. A. Martin, of Boston, is confined to two cases. In both of these cases the operations were performed as preliminary measures to facilitate the continued administration of anæsthetics, and to guard against the entrance of blood into the bronchial tubes in protracted and bloody operations involving the nasal and buccal cavities. In each instance the practical result was, in the highest degree, satisfactory, as compared with the operation as ordinarily performed with the introduction of a tracheal tube. The opening into the trachea was larger and more direct, not liable to be clogged with mucus, and unattended with the irritation which is often occasioned by the pres-

ence of the tube. The fauces being distended with a large sponge, having a strong cord attached to it, and hanging out of the mouth, scarcely any blood found its way into the trachea. The small quantity which escaped into the respiratory tube was readily absorbed by a small sponged attached to a handle. The apparatus for administering the anæsthetic was applied over the tracheal opening as often and as long as was found to be necessary, and without interfering in any way with the progress of the operation. As far as my limited experience in these two cases will warrant an opinion, I am disposed to recommend, in the strongest terms, the operation without the introduction of a tube.

When tracheotomy is performed for the relief of obstruction to the introduction of air through the larynx, and where the opening is required to be maintained for a considerable time, it is possible that practical difficulties may be encountered in maintaining the opening without the tube. But I am strongly inclined to the opinion that such difficulties may be obviated by carefully attaching the skin to the tracheal opening by a number of fine sutures.

I am fully persuaded that the use of the tracheal tube is a source of irritation, and that it is very desirable to dispense with it if the object of the operation can be accomplished without it.

Medical Gymnastics for the Phthisical.

Dr. Drachmann, of Copenhagen, who is the director of a medical gymnastic institution, to which a number of young, anæmic, slender girls are brought from the age of nine to fifteen or sixteen years, has generally found in these subjects an arrest of development in the thorax, as well as insufficiency of the respiratory movements. He therefore proposed to himself the question whether it was not possible to develop the respiratory organs by the application of methodical and judicious gymnastics of the respiration, pursued for a certain time, and also whether there were any means of verifying this development. If the results were successful, he thought the plan would furnish a prophylactic against phthisis, to which disease a greater or less number of the young patients would be liable sooner or later. In a series of investigations made by the aid of the spirometer and the stethometer, Dr. Drachmann examined the vital capacity of the lungs and the space occupied by the movements of the thoracic cavity during respiration, his researches being conducted on healthy subjects of different ages and both sexes, and also on phthisical subjects in different stages of their disease; and he has compared the results thus obtained in a series of tables (*Nordinskt Medicinskt Arkiv*, vol. xii, 1880). The general conclusions he draws are important, and they are chiefly as follows: However great may be the differences in healthy subjects, the stethometric measurements, are, as a rule, greater in every direction than in the phthisical, even in the incipient stage of the disease. The stethometric and stethoscopic results do not always agree, the latter only showing the presence of alterations in the apices of the lungs, while stethometry shows a notable diminution of the whole space of the pectoral cavity; but, on the other hand, the discovery by the stethoscope of considerable alterations of the pulmonary tissue has always agreed with the stethometric indications. In certain cases stethometry is capable of discovering incipient phthisis before this can be done by the stethoscope. As a result of his tabulated researches, including the history of one hundred cases, Dr. Drachmann shows that, with few exceptions, the young girls under his treatment improved, both in respect to the vital capacity of the lungs and in the dilatation of the respiratory surface of the thorax, so that children often entered the institution as abdominal breathers, and went out as thoracic breathers.

The Nature of the Green Vomit.

The chemical and microscopical nature of green vomit has been made the subject of recent investigations by Dr. F. Betz (*Mémorabilien*, in London *Medical Record*). It was supposed that the green vomit (*vomitus æruginosus*) was the result of a greenish discoloration of brown biliary pigment, caused by the acid action of the gastric juice. The supposition received corroboration from the bitter taste of the vomited matter, associated with its acid reaction. Dr. Betz concludes, however, that the green color is not invariably due to the presence of bile. The color often varies from a yellowish-green or grayish-green to a grass green or dark-green, in accordance with the greater or less amount of the "green substance" and other admixtures. If green vomit be allowed to stand in a vessel, the greater part of the greenish substance will sink, whereas a small portion, containing slime and fatty matters, will float on top. Shaking with water shows that the green substance is heavier than water and insoluble in it, a proof that bile is not the cause of the color. Agitation with chloroform or ether likewise demonstrates this, for neither fluid takes up the green substance. It may, however, be isolated by shaking with ether in a test-tube. This manipulation results in the appearance of three strata, an upper one, consisting of ether; a middle one, composed of the green substance; and a lower one, containing the gastric mucus. Strong sulphuric acid produces a red color; strong nitric acid leads to a yellowish discoloration of the green substance. Acetic acid develops and fixes the green color very completely. Tincture of iodine produces a yellowish-brown, and not a blue tint. Alcohol dissolves the green substance. In some respects it resembles the chlorophyll of plants. The alcohol dissolves it, and even retains the green color when boiled. The green vomit may be kept for months, and during the hot season, without spontaneous putrid fermentation taking place—a fact which militates against the possibility of its biliary or even animal nature. Dr. Betz also states that sometimes the green vomit has a neutral or alkaline reaction. Microscopical examination shows the green substance to consist of an amorphous, finely granular, greenish mass. Discoid heaps, or rounded colonies, are commonly observed. But the green substance may also form a lining over epithelial cells, salivary corpuscles, etc. From these facts

Dr. Betz infers the vegetable nature of this substance, and he adds that it is probably derived from punctiform algæ, which he calls *chlorococcus*. He denies any relation of this low fungus to other microphytes, such as the torula cerevisiæ, sarcina ventriculi, or oïdium. Finally, the author remarks that, apart from all other considerations, the frequent occurrence of copious green vomits would go to show that bile could not find its way into the stomach in such enormous quantity. The bitter taste of the green vomit receives its explanation, in part, from the frequent admixture of some bile, but it is also in part due to the presence of a bitter principle in the chlorococcus.

On Pain in the Side

At a late meeting of the Toronto Medical Society Dr. Phelan read a paper upon this very frequent symptom, which often warns us of incipient phthisis and other grave organic lesions. He mentioned a case where a lady had been examed by him for "pain in the side" at 10 P.M., and although a physical exploration of the chest could not explain the cause, she died before morning, from hæmoptysis. It is a common source of complaint in coal-heavers and grain-shovelers, from excessive use of the pectoral muscles, and a few days' rest generally effects a cure. In asthmatic patients it frequently arose from strain upon the diaphragm, and he had found a hypodermic injection of morphia give prompt relief by resting the muscle in question. The old pleuritic adhesions are a frequent cause of this symptom. When on the left side it is often due to disease of the spleen, and morbid conditions of the blood may be detected by the microscope in many cases. In hysterical females it is very common, and a placebo of chalk will in these cases at times remove the pain as speedily as a morphia powder. In conclusion he mentioned the case of Paul Broca, who, although dying from a thoracic aneurism, complained only of a "pain in the side."

Reviews and Book Notices.

BOOK NOTICES.

A Treatise on the Materia Medica and Therapeutics of the Skin. By Henry G. Piffard, A.M., M.D. Wood & Co., New York City.

A Treatise on Diseases of the Joints. By Richard Barwell, F.R.C.S. Second Edition. Wm. Wood & Co.

These two volumes are members of the series of Wood's Library of Standard Authors. Dr. Piffard's work is divided into two parts, the first embracing all the drugs which he has found recommended in diseases of the skin; the second part treating principally of the diseases, considered under the usual headings, definition, etiology, diagnosis, prognosis and treatment. A bibliography and formulary are added.

Barwell's Diseases of the Joints, the first edition of which was published many years ago, has long been a standard work on this subject, and the present issue has received a careful revision and considerable enlargement. The two volumes are both useful additions to a medical library.

The Principles and Practice of Surgery. Being a Treatise on Surgical Diseases and Injuries. By D. Hayes Agnew, M.D., LL.D., Professor of Surgery in the Medical Department of the University of Pennsylvania. Vol. II. 8vo, pp. 1066. Philadelphia, J. B. Lippincott & Co., 1881. Cloth. Price $7.50.

This volume carries the great surgical treatise of the author from chapter xi, to chapter xxiii inclusive. On the appearance of volume I we gave a full analysis of the author's plan and the extent of his treatment of the various departments of surgical science, to which we would refer the reader. (Reporter, volume xxxix, p. 385). There will appear still a third volume, which is announced to be "in process of rapid preparation," and which will complete the work.

The present volume has the chapters on dislocations, diseases of the joints, excision of joints and bones, venesection, general considerations with regard to operations (as preparation of patients, dressing, after treatment, diet, etc.), anæsthetics, amputation, shock and traumatic fever, furunculus, injuries and diseases of the genito urinary organs. surgical diseases of women, surgical affections of the spinal region, malformations of the head, and surgical diseases of the mouth.

As above noted the volume has nearly 1100 pages, large size, and it is embellished with 789 wood-cuts. Every subject is treated with a great deal of thoroughness, and representing as it does the work substantially of one man, and one closely occupied with practice and lectures, it gives us a striking instance of the success of earnest and constant labor. As to the merits of the treatise, from a scientific point of view, the reception of the first volume has rendered an opinion unnecessary.

The Kansas Medical Directory. By F. F. Dickman, M.D. For sale by the author, Fort Scott, Kansas. Price $2.00.

This directory furnishes a tabulated list of the physicians in Kansas, arranged by counties, and indicating to some extent the professional standing of each. The medical societies are also given. It is a useful volume for the purpose for which it is designed.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER-GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE SOCIAL STATUS OF THE MEDICAL PROFESSION.

It has always been a grievance with the profession in Europe. that its social position has been placed too low. Of the three so-called "learned" professions it ranks the lowest, and it never has pretended to equal the military or diplomatic service. The bar and the pulpit, the sword and the gown, have, in all periods of English history, overslawed the medical man. No physician or surgeon has ever been raised to the peerage; while necessarily admitted to the most intimate personal relations with illustrious personages, he is forced, on public occasions, to concede precedence to every class his equal in learning, and to many his inferior.

There is reason in this. The medical man is a manual laborer, a "chirurgeon," literally a "hand worker;" his proceedings are "maneuvres," works of the hand; his art is that of a skilled laborer whose success lies in his manual dexterity; and his work is none of the cleanest. Sir Astley Cooper was spoken of for the peerage, but a proud noble condemned his chances by asking who would want a peer of the realm ready, for a guinea, to examine a rectum with his finger? A famed obstetrician was seeking the same honor, but was rebuffed by the satirical observation of a peer, that the petitions to him would be extracted from the Litany, "Good Lord, deliver us."

Another reason is that he is a tradesman. His hand is extended for the shilling which he earns. This is not the case with the English barrister. His fees are not tendered him by clients, but indirectly, through attorneys. In this immediate grasping for money, this direct contact with lucre, there is believed to be something deteriorating, disennobling—and so there is. It was long ago expressed by one whose words have never been successfully disputed, that the direct pursuit of money has something in it inconsistent with the best and finest developments of human nature.

Nevertheless, the English profession is restive under this state of things. The *Lancet* complains, in a recent editorial:—

"The place of the medical profession in a high state of civilization is not yet fully defined, and the deference which is its due, by every proper criterion that can be applied, has not yet been accorded to it. On the Continent the medical profession is rather a recommendation to political place and honor than otherwise. Here, hitherto, by statesmen it has been lightly esteemed."

Not long since, Dr. J. MILNER FOTHERGILL excited the intense ire of some of his associates by describing in a series of letters to an American contemporary the present low social position of the country doctor in England. In fact, his statements were correct, and could not be otherwise when we take into consideration the slender income of the average rural physician and the financial exigencies of higher social life.

It is not better in Germany. The physician there is far from holding an equality with even the inferior nobility. It has been a matter of wondering comment that a few have married into the higher classes. Last year Dr. WILM, an eminent physician of Breslau, married a Princess of Wurtemberg, greatly to the disgust of her relatives, no one of whom, probably, was his equal in education and mental vigor. He now runs a good chance of a professorship in the University of Breslau, and enjoys an extensive practice there. The celebrated surgeon, Prof. ESMARCH, is another of the few instances. His wife is aunt to the Princess VICTORIA, of Schleswig-Holstein, now affianced to Prince WILHELM of Prussia, heir to the imperial throne of Germany.

Such examples are extremely rare. Probably it is in France that the distinguished physician obtains the highest social awards. There is a directness about the French mind which seizes the relations of social life more quickly than any other. The French are and always have been leaders in this. Their example will in time be followed by other nations.

In this democratic country of ours such invidious distinctions do not obtain. There are no discriminations against any honest avocation. The man is judged by his merits and the success which they bring him. He gains whatever social life has to offer without difficulty, if he makes it an object to do so. He is little the better for belonging to a learned profession, and certainly nothing the worse. This, we may take it, is the proper light for him to be viewed in.

THE EDUCATION OF THE PUBLIC IN HEALTH MATTERS.

The importance of taking measures for the public health is strangely undervalued in the United States. Ever so many States have no Boards of Health, no Bureau of Vital Statistics, no regulations for vaccination, in short, not a single active law on their Statute Books looking to saving their inhabitants from preventable deaths. Outside of Basuto land and similar regions, no such dense ignorance and gross carelessness prevails.

What we need in every State, and in every town and city, is properly qualified officers, who will take charge of the collection of vital statistics, the study of epidemic diseases, the regulation of quarantine, the registration of disease, the employment of experts in judicial investigations, the enforcement of vaccination and revaccination, the inspection of schools, factories, prisons and asylums; the organization of hospitals, the examination of the food supply in all its branches, the analysis of waters, and a score of other matters, which any one will see should come under the supervision of the State.

Not only through official bodies of the kind referred to, but through private organizations, must the level of health be raised to the requirements of an enlightened sanitation. In this category come all associations which aim to give reason the preëminence over passion and custom. The temperance clubs, cooking schools, health societies, and such bodies, all work toward the same end of improving the physical well-being of man by instilling self-control and a judicious use of the means of sustenance and enjoyment at his command.

Again, there are the numerous popular books upon health, hygiene and kindred subjects, which aim to teach the mass of readers the

laws of life and health. Some years ago there was a prejudice in the profession against this class of works, and consequently their preparation was left to inferior men and enthusiasts, who often advocated absurd theories or disseminated imperfect statements. The last ten years have witnessed a great change. It is no longer a questionable act, but a decided credit for a physician to write a successful book on physiology and hygiene, so that at present that class of publications presents excellent instances of sanitary readings. We have but to refer to the Health Primers, one series issued in London and another in Philadelphia, to illustrate the truth of this statement.

Lectures and journals, instruction in public and private schools and through the columns of the newspapers, are other means aiding in extending the knowledge of the laws of health. Probably these are the least perfect of the methods we have mentioned. Certainly one often meets advice in the newspapers which is quite comic, but which might be tragic were it put into practice.

The distribution of brief, plainly worded tracts on health has been successfully practiced by the National Health Society of England. Very properly, many of these are directed to instructing mothers in the care of their children. The Society very properly urges that those who are duly alive to the dangers with which their own children are surrounded, must, or ought to be, anxious to assist others less wise than themselves; and it is with this object that, among other means, simple lectures are arranged by this Society for the poor women of the crowded districts of London, who are, for the most part, ignorant of the perils to which their children's lives and health are exposed from causes under their own control. The whole aim of the National Health Society in spreading established knowledge and encouraging its practical application, whether among rich or poor, is eminently in accord with science, and conducive to the general good; and is deserving, therefore, of support and imitation. But few more ample fields for its work can be found than that which is here treated of; for it is in matters such as these, where error often renders cure impossible, that the most fitting application is found for the Society's motto, "prevention is better than cure."

Much good has been accomplished by this Society, but the field is wide and the laborers are comparatively few.

Our nation is a scattered one, but it is also a reading one. Actual illiteracy is rare. The colporteurs and canvassers of books penetrate the most secluded counties. In this way sound thought can be diffused everywhere, and if it is supplied in attractive shape it will accomplish vast good. There is great need for it, and nothing so much as it could be suggested which would add to the happiness of mankind.

Notes and Comments.

The Cause of Rigor Mortis.

This question is discussed in a recent paper by Prof. Latham, of Cambridge, England:—

Muscle during life has an alkaline reaction; but after death it becomes acid, owing to the development of lactic acid. This substance, Dr. Latham points out, may be derived from the glycogen of the muscular tissue, or from alanine, a substance metameric with sarcosine; and he suggests that it may be set free by the removal of the controlling nervous power. In muscular tissue, he holds that there must always exist the elements of (1) urethane; (2) cyanic ether + water; (3) urea. When the nerve-force is cut off by death, the decomposition of (1) and (2) would produce sarcosine, which might be sufficient to account for *rigor mortis;* or it may be that this rigidity is increased by the combination of cyanic ether with urea, producing a crystalline compound. Professor Latham thinks that the action of salicylic acid in rheumatism may be explained by its entering into combination with the elements of muscular tissue in the process of disintegration, and so preventing the formation of lactic acid.

Ergotine in Coughs.

A correspondent writes to the *British Medical Journal*, January 29th:—

Ergotine, injected hypodermically, in doses of from one to three grains, is a remedy of notable power in allaying coughs of various lung conditions, and in diminishing sputum. Unlike some

potent drugs, that occasion general distress out of proportion to possible good results, ergotine is not followed by any constitutional disturbance. However injected. there is local irritation; if into the subdermal connective tissue, suppuration may take place; it should be thrown deeply into a muscle, as the deltoid. In a small proportion of cases it entirely fails. Sedative effect persists for a day or two; is likely to control a cough that has defied even the most cunningly devised linctus.

In the severe harassing cough of advanced phthisis, not unfrequently exciting sudden fatal hæmoptysis, ergotine is indicated as a prophylactic.

The internal administration of the liquid extract of ergot, in moderate or tolerably large doses, does not seem to have the same effect.

Morbid Sweating at the Menopause.

In a recent thesis by Dr. Bouveret, it is stated that habitual general sweating may show itself in variable and ill understood etiological conditions. One of the most interesting is that of the menopause, which M. Liégeois has studied very completely. It is well known that, at the menopause, women are subject to flushes of heat and sweating; but what is less known is, that these sweats, though independent of any other affection, may become morbid. It may not be the case always of women who no longer menstruate: the hyperidrosis may come earlier, and appear when the near approach of the menopause announces itself by certain irregularities of menstruation. It is not always a passing symptom; M. Liégeois cites several cases where women were affected by it for several years; he was able, however, in most cases, to check it by the use of atropine. In most of these patients the hyperidrosis appeared especially towards the end of the night. M. Liégeois advises the administration of atropin some hours before the expected return of the sweating. Half a milligram is a sufficient dose; it is well to continue the medicine several days after the cure.

The Detection of Coffee Adulterants.

It is said that over three million pounds of chicory are imported into the United States annually, to be used in the adulteration of coffee. Dandelion root is also largely used. A British chemist states that these substances are readily deprived of color by a weak solution of chloride of lime (hypochlorite), and that this agent has very little action on the coffee. When this method is adopted, a portion of the coffee should be gently boiled a short time in water, with a little carbonate of soda, so as to remove extractive as much as possible; after subsidence the liquor should be poured off and the residue washed with distilled water. When this has been sufficiently done, a weak solution of the hypochlorite of lime is to be added and allowed to remain, with occasional stirring, until decoloration has taken place, which will probably be in two or three hours. The coffee will then form a dark stratum at the bottom of the glass, and the chicory a light and almost white stratum floating above it, and showing a clear and sharp line of separation.

The Dangers of Vaginal Injections.

At a meeting of the New York Obstetrical Society (N. Y. *Medical Journal*) Dr. Chamberlain alluded to several cases in which so much pain had followed vaginal injections of hot water that the use of them had to be suspended. In two patients they had seemed to cause perimetritis. One of these patients was under treatment for metritis and parametritis, and the os was patulous; in the other case there was stenosis; in neither was there any reason to infer that water had entered the uterus, for there was no quick, after coming uterine colic, but rather a slowly developing pain and tenderness. In order to guard against active or passive ingestion of water, he commonly advised that the patient should take the half-sitting posture, with the perineum at the edge of the couch or bed, and use the fountain syringe, with a nozzle closed at the end. Care not to insert the nozzle too far was also enjoined. He believed that, in the cases mentioned, the perimetritis was developed by the direct action of the heat—a thoroughly exceptional result, and yet worthy of note.

Chian Turpentine in Epithelioma of the Cervix Uteri.

The N. Y. *Medical Journal* states that at a recent meeting of the New York Obstetrical Society Dr. Polk related the case of a woman whom he saw last spring, who was suffering from continuous and rather profuse metrorrhagia, and in whom all the physical signs of epithelioma of the cervix were recognized. Chian turpentine was ordered, and she continued it through the summer—twenty-five grains a day. From May to September there was no change of the physical features of the affected part, but the patient's general condition improved. September 15th, she

entered the hospital. Up to that time the hemorrhage had been slight, but almost continuous. Since that date, still taking the turpentine, she had lost blood only about five days in each month, and a leucorrhœa with which she had been affected was decreasing. Physical examination, yesterday, showed the cervix very much smoother, with but few distinct nodules, and rather rough manipulation was required to produce even slight loss of blood.

The Active Principle of Hydrastis.

At a recent meeting of the Pharmaceutical Society of Philadelphia, Dr. L. Wolff made some remarks upon an improved method of obtaining the alkaloids of *hydrastis canadensis*, which he thought worthy of notice by those making them. It consists in exhausting the root of the fatty oils by percolating with gasolin before proceeding to prepare the alkaloids; the advantage derived by this procedure is quite considerable; the purification and crystallization of the hydrastia is effected with greatly less trouble. An inquiry was made whether hydrastia had any remedial powers other than those of the tonic effects of the berberina associated with it, which was answered by a positive statement that the astringent effects and the control of unnatural discharges were due to the hydrastia, while berberina had a remedial power as a tonic and cholagogue of its own.

Diarrhœal Disorders of Infancy.

Our correspondent, Dr. L. A. Davidson, of West Virginia, writes:—

I offer the following as a remedy in diarrhœal disorders of children, when the child has passed dentition, and diarrhœa has been protracted some time, through summer heat:—

℞.	Syrupi sacchari albi.,	℥ j
	Pulv. rhei,	℥ j
	Sodii bicarb.,	℥ iss
	Pulv. calumbæ,	
	Pulv. pepsin Americanæ, āā	℥ ij
	Tinct. capsici,	gtt. xxj. M.

One teaspoonful, every other time the bowels move, in *new, cold, alkaline milk* (as can be had in rural districts.)

To Relieve Burns from Mineral Acids.

An exchange quotes from the *Bulletin de Thérapeutique* the details of a serious accident which occurred during a chemical lecture, in which two students were seriously injured in the face by the explosion of a flask containing boiling sulphuric acid. The remedy applied was a soft paste of calcined magnesia and water, with which the face was covered, in layers two millimetres in thickness. The intense suffering which was first experienced ceased entirely about a quarter of an hour after the application of the remedy, and although the magnesia requires to be renewed in the course of twenty four hours, in the case of a severe burn, the patients, after recovery, retain no marks of the accident.

Special Reports.

NO. IX.—OPHTHALMOLOGY.

BY C. S. TURNBULL, M.D.

(*Continued from page* 415.)

To Dr. R. O. Born we are again indebted for a translation from the German for the second half of 1879. (*A. f. O.*, Vol. ix, No. 4.)

Carl, *A Case of Duboisine Intoxication* (Z. M. 1879, p. 337). After 3–4 drops of a one per cent. solution, dryness of the throat, somnolence and delirium, lasting several hours (in a child) (Comp. Jones, also Seely p. 000).

Doyer, on *Atropine*, *Daturine*, *Duboisine*, *Eserine*, *Gelsemine*, *Pilocarpine* (Internat. Med. Congr., Amsterdam, *C. f. A.*, p. 308), says:—

The action of eserine has a relation to pilocarpine as 32 : 1. Small doses of eserine act only upon the pupil, not upon the accommodation. Small doses of pilocarpine act upon both. The myopia after eserine is higher, but of shorter duration than after pilocarpine; the myopia from eserine can reach five dioptrics. The action of pilocarpine has passed off after twenty-four hours; that of eserine lasts four days. A minimum dose of gelsemine acts after one hour, and its action disappears after two hours; atropine acts after one, ceases after twenty-four hours; daturine acts after 1.7, ceases after twenty-four hours; duboisine acts after 2.5 and ceases after twenty-four hours. In all of them the mydriasis precedes their effect upon the accommodation.

H. MacNaughton Jones, on *Eserine*, *Pilocarpine*, *Duboisine*, *Gelsemine* (Brit. Med. Assoc., Cork, August 5–8, 1879. *C. f. A.*, p. 238), recommends the hydrobromate of eserine in marginal corneal ulcers, in perforation of the cornea, in traumatic keratitis, in suppuration of the cornea after extraction, in mydriasis, diplopia, asthenopia, disturbances of accommodation, glaucoma. Gelsemine (0.3 : 30.0) for ophthalmoscopic purposes, on account of the short mydriasis.

Landesberg, on *The Therapeutic Use of Eserine in Glaucoma* (*A. O.*, Vol. viii, p. 264), says:—

"Eserine is not only an unreliable but also a very dangerous remedy, since, by its primary results, it may lull the patient as well as the

attending physician into a delusive security, endangering thus the favorable chances of another more efficacious therapeutic action. Our first indication in glaucoma must still be the operation."

He also speaks of *The Therapeutic Use of Jaborandi and Muriate of Pilocarpine in Eye Diseases* (*A. O.*, Vol. VIII, p. 118):—

"Both are effective in the absorption of intraocular hemorrhages, opacities of the vitreous and serous effusions. It is advisable to begin at first with the smallest dose and to act afterward according to indications. Subcutaneous injections of pilocarpine are generally better borne than the internal administration of jaborandi. In regard to the myotic qualities, eserine is greatly superior to pilocarpine."

SEELY, *On the Use of Duboisine* (*A. O.*, Vol. VIII, p. 79), says:—

It does not irritate the conjunctiva, but it is liable to produce constitutional symptoms. A three-grain solution will answer any purpose.

FANO has cured hysterical amblyopia by antispasmodic remedies (*J. d' O.*, Vol. VII, p. 38).

HANSEN mentions corneal abscess as cured with the actual cautery. (*Hosp. Tid.*, 1879, Nos. 11 and 12.)

SATTLER recommends, in keratitis, antiseptic treatment and the use of the actual cautery. (*Ber. d.* 12, *Vers. d. Ophth. Ges.*, *Z. M.*, Vol. XVII.)

BEAUMETZ has cured hysterical blindness with metallo-therapeutics and electricity. (*Gaz. des Hôp.*, Nos. 55 and 56.)

HIRSCHBERG reports the *Successful Removal of a Piece of Iron from the Eye with the Electro-Magnet.* (*Berl. Klin. Wochenschr.*, 1879, No. 46.) "He speaks of the removal of foreign bodies from the eye with the magnet, and of the scleral sections made for that purpose. Real triumphs are gained with the magnet only in those cases where we have to deal with a piece of iron which has but recently entered and is suspended in the vitreous, and which, with forceps, hooks, and spoons, can but rarely be removed without permanent damage to the eyeball."

MANCHE wants to use the magnet also for the extraction of foreign bodies from the iris and the surface of the lens. (*A. d' Ophth.*, H. 2 and 3.)

The reviewer (H. Magnus) wishes to recall the fact that, for the extraction of iron splinters from the cornea, the magnet had been used as early as 1646, by Fabricus Hildanus, and, as he expressly mentions, at the suggestion of his wife. (Comp. Fabr. Hildani, opera observationum et curationum. Frankfort-on-the-Main, 1646; Cent. 5; Obs. 21.) Unfortunately, just for that purpose, it was as unnecessary as ineffective.

BOWMAN says, in speaking of glaucoma, that sclerotomy is preferable in many cases, but leaves undecided in which.

Before the operation, eserine; during the operation, anæsthesia; later, especial care that the bandage is not too tight. (Inter. Med. Congr., Amsterdam, 1879.)

JANY, on the *Effect of Sclerotomy* (Ber. de 12. Vers. d. Ophth. Ges., Z. M., vol. XVII), recommends Graefe's knife, which he prefers to Wecker's sclerotome. When eserine does not act and when the anterior chamber is very shallow, he finds this operation counterindicated.

KNAPP reports, with remarks, on a *Sixth Hundred of Cataract Extractions*, performed according to v. Graefe's method (*A. O.*, vol. VIII, p. 200), with important observations on *peripheric capsulotomy.*

KNAPP records *A New Operation for Entropion and Trichiasis.* (*A. O.*, vol. VIII, p. 249.) Incision along the upper margin of the tarsus, removal of a strip of the muscular layer, three mm. broad; then application of four sutures, above and below, only through the skin of the lid, but in the depth through the aponeurosis upon the upper third of the tarsus, in order to unite the skin of the lid firmly to the upper margin of the tarsus.

HOTZ remarks, *On the so-called Ptosis Atonica*, concerning its nature and treatment. (*A. O.*, vol. VIII, p. 400.) He unites the skin of the lid with the upper margin of the tarsus in a similar manner as in his entropion operation.

SNELLEN writes, on *The Antiseptic Method in Eye Operations* (Intern. Med. Congr., *C. f. A.*, p. 310), the lids and also the hands of the operator are washed with a two per cent. solution of carbolic acid. The instrument must be disinfected with alcohol, not with carbolic acid, *which makes them blunt.* No spray.

APPIA and GUNNING: In considering *Trachoma*, Gunning states that in Amsterdam trachoma occurs among Christians in three to four per cent.; among Jews in forty to fifty per cent. (Intern. Med. Congr. 1879. *C.f. A.*, vol. III, p. 310, with remarks of *Hirschberg.*)

EPSTEIN states *the frequent coincidence of puerperal septicæmia* with *blennorrhœa neonatorum* (*A. f. K.*, vol. I, p. 44).

GALEZOWSKY thinks that in blennorrhœa of the conjunctiva, the density of the connective tissue in adults causes sphacelus of the cornea (*Rec. d' Ophth.*, July, 1879).

MARTIN, GEORGES, thinks the *Keratitis of Harvesters* is the same process as hypopyon or ulcus serpens (Intern. Med. Congr., Amsterdam, 1879, *C. f. A.*, vol. III, p. 312).

OELLER notes the occurrence of *Retinitis and Purulent Cyclitis in Cerebro spinal Meningitis* (*A. f. A.*, vol. VIII, p. 357).

Beaver, Daniel, records a case of *Sympathetic Ophthalmia* of unusual interest, with general remarks, and we would recommend those seeking practical advice upon this disease to refer to vol. xl, p. 225 (1879), of this journal, and read Dr. B.'s article.

Angear reports a case in which there was *forty-eight hours of blindness at the parturient period*; twelve hours before the confinement, absolute amaurosis; twenty-four hours later, perception of light; after the lapse of again twelve hours, absolute recovery of sight without any objective changes (St. Louis *Med. Surg. Jour.*, vol. xxxvi, 1879).

Berlin on *Visual Disturbances after Injuries to the Skull* by blunt instruments. They are mostly one sided, occur suddenly, mostly as amaurosis, and are incurable. Among 126 cases there were 89 fractures of the base of the skull, and of 80 fractures of the orbit there was in 54 a lesion of the optic foramen, and in 42 cases hemorrhage into the optic nerve sheath. The rare double-sided disturbances of vision are not so much due to fracture of both canals as to fracture of the sella turcica (Ber. der Ophth. Ges. z. Heidelberg, p. 9, 1879).

Parinaud (De la névrite optique dans les affections cérébrales). 1. A case of hydrocephalus with double neuritis; 2. Tumor of the cerebellum, double neuritis with normal acuteness of sight; 3. Tumor of the left frontal lobe without neuritis; 4. Multiple tubercles of the brain and hydrocephalus; choked disc in both eyes; 5. Fracture of the skull, hemorrhage into the piamater, the fourth ventricle and the sub-vaginal space of the optic nerve; slight opacity of the optic discs. The author comes to the conclusion that the different intracranial affections can produce choked disc only when combined with hydrocephalus. The latter must even be considerable and find a sufficient resistance from the bones that the intracranial pressure may be increased. It has no immediate relation to the intra-ocular circulation. Schwalbe's theory of migration is not sufficient to explain all cases (Ann. d'Ocul., vol. lxxxii, p. 5).

Wolfe thinks that *the Excessive use of Tea is one of the causes of Fluidity of the Vitreous*, and ascribes the injurious influence to tannin (Brit. Med. Assoc.. Cork, Aug. 1879).

Gjersing reports *Frequent Occurrence of Cataract* in a peasant family. Among twenty-six members of the family, twenty had cataract. (*Ugeskrift f. Läger*, R. 3, B. 26, No. 18.)

Morton, Stanford, reports *Congenital Displacement of both Lenses, occurring in* several members of *one family*. (*Ophth. Hosp. Rep.*, Vol. ix, No. 3, p. 435.)

Graefe, A., on *Myopia and Divergence*, against the view of Donders, maintains his theory that the slight demand on the accommodation, which naturally exists in the myopic eye, is the main cause of latent divergence. (*Bresl. Arztl. Zeitchr.*, Vol. i, No. 7.)

Nicati, *La myopie dans les écoles de Marseille*; 3434 examinations. The Israelites showed a higher percentage of myopia than the Christians. Brown and black eyes are noted with 11 per cent.; blue and gray eyes with 18 per cent. (*Gaz. Méd. de Paris*, No. 38.)

Landouzy, ("*De la déviation cojuguée des yeux, et de la rotation de la tête par excitation ou paralysie de la* 6, *and* 11 *paire, etc.*") claims that in the former affection the patients direct their eyes and head toward the side of the paralyzed limbs, but that paralytics have a tendency to turn their eyes and head toward the affected side of the brain. (*Progr., Méd.*, Nos. 36, 37, 41, 43, 46.)

Galezowsky mentions cases of *Syphilitic Orbital Tumors*. He thinks they are characterized by their rapid development, and are mostly accompanied by periorbital pain and paresis of some or most of the ocular muscles. The optic nerve is rarely affected; atrophy of the o.d. can be the result. Periostoses and exostoses are rarely limited to the orbit; they occur in acquired and congenital lues. (*Rec. d. Ophth.*, Août., 1879.)

Schlafke. *The Etiology of Pulsating Exophthalmus*. Upon the post-mortem examination of one case where the left carotid had been ligated, and where a rupture of an aneurism of the carotid in the cavernous sinus was found, he tried to bring all the fourteen cases in which an autopsy had been made under the head of rupture of the carotid in the cavernous sinus; where, however, the interpretation of some autopsies seems forced. The rupture can be the consequence of a direct injury, or of a rupture of an aneurism, or of blood vessels which had been diseased by syphilis or atheromatous degeneration. Literature of 93 cases. (*A. f. O.*, vol. xxv, 4, p. 112.)

Becker, O., on *The Relation of Eye Diseases to the Localization of Cerebral Disease*. Conclusions: 1. In cerebral diseases, the affection is always on both sides. 2. Neuritis, or neuro-retinitis alone does not prove the existence of central disease. 3. In primary atrophy we can recognize its tabetic nature by the shape of the visual field. 4. In hemianopsia we can also, without atrophy, accurately localize the central lesion. 5. Visual centres are in the cortex of both occipital lobes. 6. We obtain important clews for the localization, by closely studying the muscular symptoms. (Intern. Med. Congr., Amsterdam, 1879." *Wiener Med. Wochenschr.*, No. 38.)

Seely, W. W., m.d., of Cincinnati, in speaking of the treatment of chronic conjunctivitis, says:—

"Facts are accumulating all the time that even purulency does not demand the astringent caustic treatment. If such is the case, how can the milder forms of inflammation make it necessary?

"Purulent conjunctivitis was the last I had the courage to abandon the usual treatment in.

"I firmly believe that the total abolishment of these agents would add vastly to the number of eyes saved. I write in the strongest terms, not because my success with these materials has been

less than the average, but rather from the fact that my observations of the results at home as well as abroad afforded me no encouragement for continuing the old plan.

"In all cases of trachoma in which the cornea was involved, I abandoned the astringent-caustic treatment and treated the corneal complication as I would a corneal disease without any conjunctival inflammation, viz: with the yellow oxide of mercury, and atropine, if it seemed to do no harm either to the cornea or conjunctiva."

(Experience has taught us to stick to the careful, daily, touching of the entire palpebral conjunctiva with the smooth crystal of sulphate of copper; we would emphasize the word careful, by saying: Touch the entire superior palpebral trachomatous conjunctiva with the *smooth* crystal, and before allowing the lid to escape, brush its surface with *cold* water so as to wash away all of the salt and continue the bathing of the eyes for at least twenty minutes).

"For some years it had appeared to me irrational that inflammations of a membrane should be treated with a material that, in many cases at least, sets up an irritation of this same membrane, viz, atropine.

"Again, it had seemed to me that in pure corneal inflammations, atropia was by no means an infallible remedy, but often a delusion and a snare.

"In my practice eserin has quite taken the place of atropine, even in that rebellious and destructive disease, *ulcus serpens corneæ*.

"I believe it must be the most extraordinary occurrence for a corneal complication to arise during a purulent conjunctivitis, *if* all irritating epithelial destroying substances are kept away from the eyes and the discharges either constantly removed or rendered innocuous."

(The "if" in this last paragraph is a large one, because corneal complications are the rule in des purulent conjunctiviti and to keep such free from irritating discharges, or to be able to render such innocuous, is next to impossible even with intelligent patients in the hands of experienced nurses. We fully agree with Dr. S. concerning the indiscriminate use of astringents by the inexperienced, but, while accepting and recommending his substitutes, must say that we have likewise found astringents are of decided value. They should never come in contact with the cornea. *This is the point.* They should be used locally, their action limited, and (we repeat for emphasis) they should *never be dropped* into the eye as is usually directed.

"Certainly astringents and caustics can with difficulty, if at all (render discharges innocuous), and the success obtained with them must be ascribed to cleanliness, in spite of the brilliant explanations that have been given for their action. They certainly are dangerous when coming in contact with the cornea, as every one has recognized.

"Every one recognizes cleanliness as a *conditio sine qua non* in purulency, but if we accept the parasitic theory antisepsis or asepsis must be obtained, and the problem would be to discover the best material that can be used with safety.

"Finally, I cannot but regard the astringent-caustic method as irrational, dangerous and painful, and most satisfactorily finding a substitute in the yellow oxide and vaseline, a rational, safe and painless remedy."—*The Cincinnati Lancet and Clinic, December 18th*, 1880.

Our attention has of late been called to

A Most Dangerous Instrument,

now exposed for sale by the leading apothecaries of this, and we are sure, of other cities. It was originally imported from France, under the name of "Aspirateur Clyso-Pneumatique;" and has been pirated and made in this country, and called the "eye-cup." Fortunately the American copy is usually sold without directions, but this French optical blunderbuss is recommended for the painless removal of foreign bodies *from within the eye*, as useful in the treatment of all diseases of the eye, and in changing the shape of a presbyopic eye so that glasses will not be required. We have captured this terrible instrument in the hands of both private and clinical patients, strenuously advised others against its use, and have been called upon to witness retinal congestion and hemorrhage; also, lenticular corneal, conjunctival, and palpebral changes or inflammations, and in one case total blindness (from detachment of both retinæ in a boy of twelve years); all caused by the use of the infernal instrument referred to.*

By permission, we publish the following communication received from a well-known authority, Dr. Dudley S. Reynolds, of Louisville, Ky.:—

"I do not know who it was, if any one at all, who made reference to the dangers attending the use of the patent pneumatic exhausters for the eye. I have frequently called attention to the dangers attending the use of the widely advertised eye cups, the structure of which is no doubt familiar to you.

"A few months ago I had a case of traumatic

*It consists, essentially, of a glass cup, to fit the eye outside of the lids (as does the ordinary eye-glass) which opens into a glass tube, or, as in the French apparatus, opens into an expanded glass tube, or reservoir, which connects with a hollow, stiff, rubber ball. By at first compressing the ball and adjusting the glass over and upon the eye, and subsequently relaxing pressure upon the ball, a vacuum is formed, suction power is exerted and the eye may be literally drawn from its socket.

Within the past six months we have seen warning mention of this instrument made by some gentleman, before the meeting of a medical society; but, even after correspondence with many authorities, all search for such reference has been unsuccessful on our part. We should be glad to place his name on record as a public benefactor.

cataract, produced by the application of the so-called eye cups and consequent rupturing of the capsular ligament of the lens. I have now under treatment the case of a gentleman who was but slightly presbyopic, and who was induced to lay aside his glasses to try the power of the eye cups, which were highly recommended by a CLERGYMAN in the neighborhood. The unfortunate man, after the first application of the cups, had a sense of cramping in the eyes, as he called it, which was followed by dimness of vision and flashes of light, and in a short time he noticed limitation in the field of vision. He came to Louisville in a great state of alarm. Examination revealed hemorrhages into the vitreous in both eyes, and in the left eye there was hemorrhage into the anterior chamber.

"I have known quite a number of similar instances of the dangerous results of the so called eye cups, which, I suppose, are the pneumatic exhausters referred to in your letter."

CORRESPONDENCE.

Therapeutic Uses of Tobacco.

ED. MED. AND SURG. REPORTER:—

In looking up the medical uses etc. of tobacco, I find that very little mention is made in the various therapeutics of its employment as a constituent of poultices. Believing it to be a means of great value in certain painful affections, I desire to bring its use to the attention of physicians. Tobacco poultices were at one time rather generally used, but for some reason or other their efficacy has of late been lost sight of. I hope that the slight resurrection which I may occasion may prove of service to the profession.

A case or two from my note book will serve to illustrate the good effects of tobacco poultices.

Mrs. M., last fall, had intermittent fever, contracted through the ignorance of her physician in directing her, on the tenth day after confinement, to sit up the greater part of the day, and for nearly an hour to remain by an open window overlooking a large lot full of decaying leaves, weeds, animal matter, etc.

I was called in on the following day. Among the symptoms which presented themselves, I found over the chest great tenderness and pain on the slightest pressure. I diagnosed this to be due to an irritated condition of the nerves or nerve-endings; and ordered flaxseed, mush and other poultices, one after another, but without avail. The pain still continued. I then gave medicine, belladonna ointment, etc. I exhausted the list without giving relief.

I mentioned the case to my friend, Dr. J. V. Myers, of this city, who advised me to use a poultice of flaxseed and tobacco, equal parts, care to be exercised as to the toxical effects of the latter. I took advantage of the advice. The alleviation of the pain, which before the application was excruciating, was immediate and permanent. The relief was beyond my expectations. On the same patient, this same poultice has on one or two occasions since done equally good and effective work.

Mrs. J. had an attack of perityphlitis. For the pain, I ordered the usual medicines, together with mush and flaxseed poultices. These had no effect. I then had applied the poultice of flaxseed and tobacco. There was an almost instantaneous cessation of the agonizing pain from which, for two days, the patient had suffered.

I cite the two above cases, because I know that there can be no mistake, but that the tobacco was instrumental in doing the good work.

In all instances when a simple poultice does not meet with the success desired, I add tobacco to it, in the proportion of one half. The leaves are the best for the purpose; but the various kinds of clippings in the manufacture of cigars, etc., will answer. The tobacco should be cut up finely, and then well mixed with the flaxseed; the poultice is made in the usual manner. A fine piece of linen, or gauze, is to be placed between the poultice and the body. Care must be taken that the part to which the poultice is to be applied is not denuded of its skin, for the tobacco may, in such a case, give rise to symptoms of poisoning. I think, that, with ordinary care, there can be no danger; in my hands this poultice has proven of great value.

I would ask that the readers of the REPORTER employ this poultice when indicated, in the stead of the simple flaxseed poultice, and report their success or failure, as the cases may prove to be.

G. MAXWELL CHRISTINE, M D.

NEWS AND MISCELLANY.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service. January 1st, 1881, to March 31st, 1881.

Bailhache, P. H., Surgeon. Detailed as chairman, Board of Examiners, Jan. 4th, 1881.

To proceed to Barnstable, Boston, and New Bedford, Mass., and Providence, R. I., as inspector, Feb. 1st, 1881.

To proceed to Wilmington, N. C., as inspector, assume temporary charge of the Service, and superintend the re opening of the Marine Hospital at that port. March 12th, 1881.

Long, W. H., Surgeon. Detailed as member Board of Examiners, Jan. 4th, 1881.

Fessenden, C. S. D., Surgeon. Detailed as chairman Board of Survey, for the physical examination of officers of the Revenue-Marine Service. Feb. 8th, 1881.

Doering, E. J., Surgeon. Detailed as recorder, Board of Examiners, January 4th, 1881.

Gassaway, J. M., Passed Assistant Surgeon. Detailed as recorder, Board of Survey, for the physical examination of officers of the Revenue-Marine Service, Feb. 8th, 1881.

Smith, Henry, Passed Assistant Surgeon. Granted leave of absence for thirty days, from March 1st, 1881, Feb. 8th, 1881.

Upon expiration of leave of absence, to proceed to Norfolk, Va., and assume charge of the Service, relieving Surgeon R. D. Murray, March 15th, 1881.

Irwin, Fairfax, Assistant Surgeon. When relieved by Assistant Surgeon W. A. Wheeler, to proceed to Wilmington, N. C., and assume charge of the Service, relieving Surgeon P. H. Bailhache, March 30th, 1881.

Guitéras, John, Assistant Surgeon. To proceed to Key West, Fla., and assume charge of the Service, relieving Passed Assistant Surgeon Smith. Feb. 5th, 1881.

Wheeler, W. A., Assistant Surgeon. To proceed to Charleston, S. C., and assume charge of the Service, relieving Assistant Surgeon, F. Irwin, March 30th, 1881.

Benson, J. A., Assistant Surgeon. To proceed to St. Louis, Mo., and report to Surgeon H. W. Sawtelle, for duty. Feb. 5th, 1881.

Carmichael, D. A., Assistant Surgeon. To proceed to Boston, Mass., and report to Surgeon J. Vansant, for duty. Feb. 5th, 1881.

Armstrong, S. T., Assistant Surgeon. To proceed to New Orleans, La., and report to Surgeon H. W. Austin for duty. Feb. 5th, 1881.

APPOINTMENTS.

The following candidates, having passed the examination required by the regulations, were appointed Assistant Surgeons, Feb. 4th, 1881:—Duncan A. Carmichael, of New York, and Samuel T. Armstrong, of Missouri.

The Diploma of an Herb Doctor.

Among the curiosities of diploma making is the following, presented to the County Clerk of Newark, N. J., by a colored herb doctor who claimed to be 99 years old:—

SIERRA LEONE, AFRICA, 1806.

I hereby set my hand and seal, in this year of our Lord, 1806, to write a diploma according to our rules and methods. This is granted to Dr. Delaney, after going to school from seven years old until twenty-one, then studied in Mondigo Herb College five years. This diploma was on him being a competent herb doctor. This is granted by the college, and signed by the Board of Health of the Mondigo Tribe.

[Signed] Dr. IVISON BURKE.
Dr. GEO. WASHINGTON,
Dr. SIDNEY SNYDER.

Dr. Delaney is now permitted to go in any part of this county or any other county to practice. [Signed] PETER HUANTY,
Clerk of the Mondigo College.

The document was written on elephant's skin, and had five United States postage stamps on it, for seals. The applicant was referred to the Secretary of Essex County Medical Society.

American Medical Association.

During the session of the American Medical Association, in 1881, a *daily edition* of the *Virginia Medical Monthly* will be issued, giving full reports of the Proceedings of the General Sessions and of the several Sections, as well as the Proceedings of other Associations that convene at the same time and place—such as the Association of Medical Colleges, etc. This daily edition will be printed with large-face type, in double columns, on quarto pages; and the number of pages will be limited only by the amount of material to be published.

The four daily issues (Wednesday, Thursday, Friday and Saturday) will be mailed to any address in the United States on receipt of forty cents, or ten cents a copy; to any address in Europe for fifty cents.

An abstract of the proceedings will appear as usual in the MEDICAL AND SURGICAL REPORTER.

Medical Geography.

Many interesting facts in reference to medical geography will be brought out by the new census. All physicians are aware of the numerous relations which altitude bears to the origin and progress of certain diseases. The new census will show that nearly one fourth of the people of the United States live on a level corresponding with that of Philadelphia, which is from thirty-two to one hundred and forty-three feet above sea level. Three fourths of the whole population of the United States live below the 1000 feet level, and only three per cent. above 2000 feet. The great settlements are almost of necessity directly on the seaboard or on the banks of navigable rivers, and it is this circumstance that puts such a large proportion of habitations less than one hundred feet above the sea level.

How Philadelphia Cares for its Foundlings.

The Society for the Prevention of Cruelty to Children have asked Judge Hare to have investigated, by the Grand Jury, allegations that nearly every foundling sent to the Philadelphia Almshouse dies within a short time after admission, the deaths being caused by improper food and unskillful treatment on the part of pauper nurses, as well as by the exposure to which the infants have been submitted. These charges are notoriously too true; but then, it would be highly immoral to establish such efficient Foundling Hospitals as they have in Paris—say the very good people.

American Medical Association.

The Pennsylvania Railroad having agreed to issue excursion tickets to Richmond, from Philadelphia, New York, and Pittsburg, all who desire to avail themselves of the reduction should apply at once, *with stamp* for orders.

W. B. ATKINSON,
1400 *Pine St., Phila.* *Permanent Sec'y.*

The Smallpox.

Sixty cases of smallpox are now reported in the Almshouse at Reading

Glover's Gap, a village in Marion county, West Virginia, is terribly afflicted with an epidemic of

smallpox. and all the doctors there being sick with the disease, there is no one to attend to the stricken The dead are left unburied, and all who could do so have left the place. The disease has spread to Burton, ten miles distant. The Governor was telegraphed to for help to bury the dead, and replied that the county authorities should attend to the matter.

Hospital Extensions.

New hospitals, one to be under the charge of the Little Sisters of the Poor, and the other under the Sisters of St. Francis, the latter a branch of St. Mary's Hospital, are to be erected this season, the former on Mill street, near Cedar, Germantown, and the latter on the west side of Broad, between McKean and Mifflin street. Additions are now being made to the Children's Hospital, the Pennsylvania Hospital, and the Philadelphia College of Pharmacy.

Hogs versus Babies.

The *Scientific American* thinks it a pity that babies have not a market value, like hogs. A death rate among the pigs less than one-third the death rate among children in our large cities, moves the Government to costly investigations of the cause, and to diplomatic correspondence with foreign nations, while Produce Exchanges get excited on the subject, and all the newspapers join in the discussion. The babies die by the thousand in New York and other overcrowded cities, and scarcely any notice is taken of the fact.

State Medical Society of Pennsylvania.

Excursion rates to the next meeting at Lancaster will be allowed by the Pennsylvania, Philadelphia and Erie, and the Northern Central Railroads.

Those who desire to avail themselves of these rates should apply at once, *with stamp*, naming the railroad over which they propose to travel, and the number of orders required.

W. B. Atkinson,
1400 *Pine St., Phila.* *Permanent Sec'y.*

Personal.

—Dr. F. J. Baker has removed from Youngstown, New York, to Lockport, New York.

—Dr. Wm. Rutherford Sanders, of Edinburgh, died February 18th. He was an active writer for the medical press and a popular medical teacher.

—Dr. Lauderdale, of Hernando, Mississippi, and his daughter, were both fatally injured, April 12th, by a tornado which demolished his residence.

—Dr. Horatio N. Loomis, who recently died in Buffalo, New York, at the age of seventy-four years, was the oldest member of the Erie County Med cal Society, having been enrolled on its lists for forty-five years.

—The hospital at York, Pa., opens April 28th.

OBITUARY NOTICES.

DR. R. O. COWLING.

Dr. Richard Oswald Cowling, A.M., Professor of the Principles and Practice of Surgery in the Medical Department of the University of Louisville, founder and editor of the Louisville *Medical News*, died suddenly, of rheumatism of the heart, April 2d, 1881. He was born near Georgetown, South Carolina, April 9th, 1839, graduated at Trinity College, Hartford, and took his diploma in medicine at the Jefferson Medical College, in 1867. He at once began practice in Louisville. In 1868 he was appointed Demonstrator of Anatomy in the University of Louisville, and in 1870 adjunct Professor of Surgery; in 1873 Professor of Surgical Pathology and Operative Surgery, afterwards Professor of the Principles and Practice of Surgery. In 1867 he was appointed Surgeon General of the Kentucky State militia, on the peace footing. In 1876 he founded the Louisville *Medical News*, and soon after associated Dr. William H. Galt in the editorial management.

About that time (1876–7) much complaint arose throughout the country against the policy and management of the Louisville Medical College and the Nashville Medical College, on account of the charge that these two institutions had been holding two graduating terms in one year, and on account of other matters not necessary to mention. The Louisville *Medical News*, with great vigor, began a series of the most severe criticisms of these schools, which resulted in a change in their course in this respect.

Dr. Cowling was of fine physical frame, genial manners, and possessed of a witty and pleasant literary style.

QUERIES AND REPLIES.

Sir—Will some of the numerous readers of the Medical and Surgical Reporter give a cure for "Lithic Acid Calculi." Have used a great many remedies. They form and cause nephritic colic every two or three months. The patient, a male, aged 54, otherwise enjoys good health. G. B. S.

Constant Reader.—We know of no recent monograph on the subject of varicose veins.

W. S., of Pa., Asks for suggestions in a case of importance: the patient is temperate, and except flatulent dyspepsia, otherwise in good health.

A full array of the most reliable plans of treatment of this complaint is presented in Napheys' *Surgical Therapeutics.*

Sir—In answer to the query of Dr. D. Wood, in the last number of the Medical and Surgical Reporter, concerning the significance of œdema of the face and œdema of the legs, I would state that the report of my clinic was not entirely correct; the statement made by me being that if œdema first manifest itself in the face it is generally of renal origin.

William Pepper, M.D.

MARRIAGES.

BIBBY—TURNER.—On Tuesday evening, April 5th, by Rev. A. J. Rowland, D.D., Walter E. Bibby, M.D., and Miss Mary M. Turner, both of this city.

SARGENT—LEDYARD.—On Thursday evening, April 7th, at the residence of the bride's mother, in Brooklyn, by the Rev. Dr. Edward O. Flagg, Dr. Dudley Allen Sargent, of Harvard University, and Ella Fraser, daughter of the late Wm. S Ledyard.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

CLINICAL CASES.

BY WILLIAM HENRY DRAPER, M.D.,

Professor of Clinical Medicine in the College of Physicians and Surgeons, New York City.

Gastric Ulcer.

Gentlemen:—This case is one of interest, and I am very glad indeed to show it to you, because it is a perfectly typical illustration of the disease from which the patient is suffering. The case is one of gastric ulcer. Gastric ulcer is not a very common disease. The point to which I wish particularly to call your attention in her history is the history of dyspepsia. A dyspepsia depending upon a subacute gastric catarrh. She has for seven years suffered from occasional nausea, vomiting, regurgitation of sour fluids into the mouth, sour and foul taste in the mouth, eructations and flatulency, all of which are symptoms of a kind of dyspepsia which depends upon a catarrhal lesion of the lining membrane of the stomach. I wish you to note this because it is commonly out of a condition like this, out of a gastric catarrh, that you will get ultimately, in many instances, ulcers of the mucous membrane of the stomach. There are divergent views in regard to the immediate cause of ulcer of the stomach, but the only one to which I will allude now, which it is important to allude to in connection with the clinical history of this disease, is that which holds that it is dependent upon the digestion of certain tracts of the gastric mucous membrane in consequence of the withdrawal of the circulation from those tracts. This withdrawal of the circulation is supposed to be accomplished through a thrombosis or an embolism of the ramifications of the gastric artery. A consequence of the withdrawal of the circulation from these patches in the stomach is, that they become exposed to the destructive action of the secretions of the stomach. You can readily understand how this accident is more likely to occur in a congested and catarrhal condition of the mucous membrane than in the perfectly healthy condition, though it is possible that a gastric ulcer may form suddenly and unexpectedly in a stomach which has not been the seat of gastric catarrh, in consequence of one of those accidents to the circulation to which we, under certain circumstances, are liable.

In connection with a gastric catarrh from which she suffered, the urine was frequently dark and thick. That is by no means an uncommon symptom in the history of this form of dyspepsia.

We come now to the history of her present attack. On the first of this month, on waking, the patient complained of *malaise* and complete anorexia. A little later she fainted. Shortly after this, on going up stairs, she fainted again. Now, these attacks of syncope were perhaps simply the result of want of food, but more likely the result of a small hemorrhage, which did not manifest itself by hæmatemesis, but the evidence of which might have been found in the discharges from the bowel. It was not long, however, before the evidence of gastric hemorrhage was sufficiently noticable. Two days later the patient suddenly felt weak again, and vomited considerable blood of dark hue, mixed with food.

The hemorrhages which occur under these

circumstances are sometimes very large. If it happens that a vessel of considerable size is opened in one of these ulcers you may get a very large hemorrhage, and the hemorrhage is accompanied usually by a well marked tendency to syncope, and by the vomiting of large masses of dark clotted blood changed by the secretions of the stomach. Occasionally, when the hemorrhage is excessive, you may get bright blood from the stomach, but the source of blood from the stomach can generally be ascertained by its dark hue and mixing of grumous matter, food, with the blood.

The patient remained quietly in bed until last Saturday, when she had a more severe attack of hæmatemesis; since then there has been no hemorrhage.

Now we come to mention another symptom which exists throughout the history, which may exist with a catarrh, and which ordinarily pre cedes it, and which very often is distressing; I mean pain. She had suffered pain some time before this hemorrhage. It would come and go. It would come almost immediately after eating. That is the history which these patients frequently give; that it is a pain that is paroxysmal, the paroxysms, however, very commonly started by the ingestion of food or fluid. And this pain, as I said, is sometimes extremely severe. It is commonly located in the epigastrium, and the patients will complain of pain in the back. It is a boring pain, and a pain that is aggravated oftentimes, or started, by the ingestion of food. With this pain she also had a good deal of flatulency. Flatulency is a symptom that is usually developed in i s most severe degree two or three hours after the ingestion of food, and not immediately after. She also had what is not at all uncommon in connection with pain and flatulence, and distention, a great deal of cardiac palpitation. This is one of the most common of the reflex symptoms of gastric catarrh. It is not necessarily associated with ulcer, but is very frequently associated with ulcer, because ulcer is so commonly associated with a catarrhal condition. It is also noted here that the movements of the bowels following the first hemorrhage were dark and black and bloody. This is a clinical fact that is also often noticed in the history of hæmatemesis, and I have no doubt that many of her first fainting attacks unaccompanied by hæmetesis were due to hemorrhage, evidence of which might have been found in the presence of blood in the stools.

Now this history gives you a very fair, I might say a typical illustration of the evidences of gastric catarrh leading to ulcer of the stomach. You may ask whether it is possible to diagnose ulcer of the stomach where there has been no hemorrhage, the result of the opening of a vessel in the ulcer. I think it is extremely difficult. I think it is very difficult to determine absolutely that you have ulceration of the stomach unless an accident of this sort has occurred. If, however, you have a case in which the pain is paroxysmal, as it is here, in which the pain is aggravated by the ingestion of anything in the way of food or drink, if it is boring in character, if there is tenderness on pressure over the epigastric region, I think it is pretty safe to suspect very strongly the presence of ulcer. And yet, all the symptoms which I have mentioned may exist with a history of gastric catarrh. So that the diagnosis with absolute certainty of gastric ulcer where there has been no hemorrhage, and where there has been no evidence of perforation, is, in the majority of cases, impossible.

The prognosis in this case, you will judge from what I have said, affects certain accidents which are important in their results. If you have an ulcer of the stomach, there are the chances of the opening of a vessel of greater or less magnitude, and perforation, and consequently of peritonitis. This perforation of which I speak may possible lead into another part of the alimentary canal, but in the majority of instances into the peritoneum. The accidents which I have mentioned are sufficiently grave to make this disease one which should arrest your attention and lead to your best consideration in the treatment.

Now, what can be done in these cases? Much can be done to protect the patient from suffering, and also to bring about the healing of the ulcer. Various methods have been suggested in the treatment of this disease, but the principle which h s found most favor within the last few years is that of rest. This is secured by relieving the stomach of all duty in the process of nutrition, by resorting to rectal alimentation, so that the stomach shall be absolutely at rest. This principle, if it can be applied, is certainly one which will give the patient the greatest amount of comfort, and I believe the very best chances of recovery. The principle of rest, gentlemen, is a very important one to consider in the management of many diseases, and it should be considered in relation to a department in which, I regret to say, it does not seem to have obtained sufficient attention, that is, in surgery. The principle of rest in the treatment of disease generally is very frequently ignored. The application of this principle in the treatment of

ulcer of the stomach is, as you can see, a perfectly rational one. You have an ulcer which is irritable, which is painful, and which is constantly aggravated by the introduction of food and the consequent secretion of digestive fluids, and every time you put food into the stomach and arouse the organ into activity you give the patient great pain. You place the ulcer under conditions which necessarily increase it in extent, and you increase the chances of the accidents which your patient is constantly liable to meet with.

Now, is it possible to give the stomach rest? Recent investigations in the application of rectal alimentation as a substitute for gastric digestion would seem to show that the rectum is capable of doing to a certain extent the work of the stomach. At all events, you can bring certain kinds of food into contact with a very considerable tract of vascular mucous membrane, from which absorption of certain elements of food can be secured. There is considerable question among authorities as to whether the rectum is capable of digesting the albuminoids, and the enthusiastic advocates of rectal alimentation say that it is not necessary that they should be digested; that if you will use blood, for example, defibrinized, the blood-vessels will take up the blood corpuscles, they will swallow them whole and carry them into the circulation. The same enthusiastic advocates of rectal alimentation say that the mucous membrane will take up milk globules, or any other emulsionized fat. It is pretty certain that it will take up water, and that it will take up the salts in it; but, after all, the fact that a patient may be sustained for several weeks on food that is introduced into the rectum is the striking fact, and the one which justifies us in this kind of feeding, no matter what we may think as to special digestive powers of the rectum. That patients can be sustained in this way has been demonstrated over and over again. Therefore, I believe that we should continue to do it, and not allow our theoretical objections to influence us in the application of this kind of feeding. There are a great many cases of gastric ulcer on record which have been treated in this way and treated successfully. The usual result is that from the time that this treatment is inaugurated the patients cease to complain of pain and feel very much more comfortable than they had felt for a long time before they resorted to the treatment. They do not emaciate; they often retain their weight, and even gain in weight. Now, I have said that this is the case in those patients in whom this treatment is *applicable*. It so happens that it is *not always applicable*. It sometimes happens that in these cases we are not able to carry out rectal alimentation, not even by using opium in connection with the injections, as is commonly done, in order to make more sure of their being retained. This patient does not retain them. They are rejected, and we have been obliged to give this kind of treatment up. But ordinarily, in the majority of cases I think I may say, you can inject four or five ounces of milk, of defibrinized blood, of concentrated beef tea, with or without a few drops of laudanum, as often as once in four or five hours, and it will be retained.

Supposing you are not able to resort to rectal alimentation; then you have to feed the patient by the stomach and you have to choose for your food something most bland, unirritating. For this purpose there is nothing better than milk, or concentrated broths, especially broths of fowls, as chicken broth, and very little or no starchy food. If you use any starchy food you should use it in very small quantity, and for the purpose of forming large masses of coagulated milk. It is a very good plan in the feeding of children and in the feeding of invalids with milk, to introduce into the milk a certain amount of thin starch water, inasmuch as this has the property of separating and softening the curd, so that the gastric fluids can get more easy access to the whole of it. In those cases, therefore, of gastric ulcer, where you are obliged to use the stomach, it would be very well to adopt the same principle you would adopt in feeding an infant which had been taken from the breast and put upon cow's milk. The great trouble in milk feeding is that the stomach is liable to be irritated by the masses of coagulated caseine which the gastric juices cannot get at to dissolve; and it is a good plan, therefore, to resort to frequent feeding with milk which has a certain amount of starch water added to it, for the mechanical purpose that I described. It is a good plan, I say, to use milk in this way, and to use it in small quantities and frequently.

You may ask whether there is any medicine to be given to cure these ulcers? I do not know of any. You may be obliged to give opium, to control pain, but I do not know of any medicine which you can give which may be expected to exercise a local effect in the healing of these ulcers. I believe that your best success lies in rectal alimentation and in feeding with milk. There is one point, however, in the medical treatment of these cases to which I would like to call your attention, and that is the washing off of the mucus which embarrasses the digestive power of the stomach and intestines in those

cases where they are complicated, as I told you they most commonly are, by a catarrhal condition; the washing off of this mucus every morning by means of the bitter waters. These patients are very apt to be much benefited, I think, by this proceeding. Where you have a simple case of gastro intestinal catarrh, alone or complicated with ulcer, your patient will find a good deal of comfort and decided benefit, according to my experience, from taking, every morning, or every other morning, a dose of these bitter salts, either in the form of one of the natural waters or in simple solution, in sufficient quantity to produce one or two watery evacuations. I have very great confidence in this method of treating the catarrhal conditions which are so common, and which may at any time be complicated by ulcers.

This is pretty much all the medication I have to commend to you in these cases—the use of the bitter waters, the washing off of the mucus which interferes with the functions of the stomach and intestine, opium to control pain, if necessary. You may ask whether there are any astringents to be given; any medicine which may be supposed to act upon the ulcer in the stomach as the medicines which you apply to act upon an ulcer of the leg? If you are sure of your ulcer, and if you are sure of getting at it with your application, I may say that it might be a very good thing; but, as I told you, in the majority of cases you are not sure of your ulcer, and then you are not justified in making use of so large a quantity of any local application, any astringent in solution, for example, that might be supposed to come in contact with the suppositious ulcer anywhere upon the coat of the stomach. So that there is nothing but empirical medication to suggest after the rational therapeutics that I have suggested. The rational therapeutics, you understand, consist in rest of the stomach, secured, if possible, by rectal alimentation, and a less measure of rest secured by giving the patient the most bland and easily digested food that is to be found, namely, milk and concentrated broths, and opium as a medicine, and the bitter waters as a means of washing off the catarrhal mucus.

You notice that this patient is extremely anæmic, and some of the very interesting symptoms of her anæmia are noted in this history. She has the anæmic murmur well developed in the præcordial region and in the course of some of the larger arteries. You can see, from her complexion, that she is anæmic. And in connection with this anæmia certain symptoms are noted here which are specially worthy of your consideration. It is stated that the patient is very sensitive to pressure in the umbilical region, and on moderately deep palpation a distinct heaving impulse is conveyed to the hand, synchronous with the heart's systole. On auscultation at the upper edge of the umbilicus you get a distinct, loud, systolic bruit. The sensitiveness to pressure and the pulsation are such as would suggest aneurism, and yet the fact that the patient has recently had severe hemorrhage, which is very apt to be followed by marked and perceptible pulsation, is, I think, the most probable explanation of this pulsation. She is young to have abdominal aneurism; she has not the diseased condition of the arteries which is apt to be found in abdominal aneurism; she is a woman, and so far is not likely to be subject to this disease, the majority of subjects of abdominal aneurism being men. Therefore, I am inclined to believe that we should exclude the idea both of heart disease and of aneurism which the murmurs heard in the region of the heart and the murmurs and the pulsation observed in the abdominal aorta might suggest.

The note made of this patient to day is that she is very hungry. This is a symptom which these patients not infrequently complain of, especially if they are (not?) nourished by the rectum, but you have to be very cautious. There is room for a vast amount of judgment and tact in the feeding of these patients. You can defeat your purpose very easily by over feeding them, and it is better that they should suffer a little from hunger than that you should overtax the powers of the stomach. If they are very hungry, or if they suffer pain, you are justified in controlling this pain by the use of morphine, and the best way of using morphine is to use it hypodermically. But it is better that the patient be allowed to suffer some than that she should be allowed to use morphia in any considerable quantity.

Grave's Disease.

This woman, gentlemen, has Grave's disease, the striking features of which consist of three symptoms which she presents, namely, an excessive degree of palpitation, a moderate amount of enlargement of the thyroid gland, and a moderate degree of exophthalmus. All these three symptoms are apt to coexist in this disease, the exact nature and cause of which is not comprehended, but these three symptoms are so frequently found associated that they were described long ago by Graves and Basedow almost contemporaneously, and the disease has since been known by the names of both of those physicians.

The pathology is probably connected with the vaso-motor system of nerves. This woman, when she came here, was so feeble, and suffered so much from the cardiac symptom, cardiac dyspnœa, that she was obliged to remain in bed, and she had once or twice very severe dyspnœa from œdema of the lungs, œdema being an incident which is not unlikely to occur where there is an extremely rapid and irregular action of the heart, such as occurs in this disease. But she has steadily improved under rest and cardiac stimulants, digitalis and iron, so that she walks about the ward and has a fair degree of comfort. She still has a rather rapid and irregular heart. There are cases in which the patient can hardly get along without rest. There are cases in which you would do well to put the patient to bed, and secure rest by artificial means if necessary. You may have to give rest to the heart by diminishing the frequency of its pulsations, and this, as you know, you can do by giving digitalis, and digitalis is vaunted by several distinguished authorities as the remedy par excellence in this disease. If you will read the account of it which Cruso (?) gives, you will be led to believe that digitalis is a remedy which is likely to cure all cases, or, at least, a majority of them, but, unhappily, I have not found in my experience that it has always acted satisfactorily. I think that, as a rule, it does give a certain amount of benefit; it diminishes the frequency and increases the force of the cardiac pulsations, and this of itself is an important factor in the cure of this disease. I have used another remedy, the iodide of potassium, under similar circumstances, with the most gratifying results in a few instances. It has been used here, and has contributed, I think, to the improvement which the patient enjoys.

Supernumerary Fingers.

Here, gentlemen, is a case of supernumerary fingers. The patient is a colored man. I will not call your attention to his disease to-day, but I simply show you that he has an extra little finger on each hand. He has no use of it. Other members of his family have the same, and it is not uncommon for supernumerary fingers and toes to be hereditary.

Pericarditis.

Here is a patient in whom you will hear a well marked friction murmur over the heart. In listening to it you will in the first place observe how superficial the sound is, and then you will observe how it is modified by the breathing, it being more distinct in expiration than in inspiration; then you will observe the creaking character of it. It is very like the creaking of new leather. You could scarcely mistake that for anything else than what it is, a pericardial friction sound. It is not smooth, like an endocardial murmur. It is varying in intensity, it is exceedingly rude, it is superficial, it is creaking in character, and it is most distinctly heard at the apex.

Now, this is another interesting example of pericarditis occurring independently of any complication, and yet it is probable the inflammation is of a rheumatic character. He says he has never had rheumatism; he is a pianist by profession. I say it is probable the nature of the inflammation is rheumatic, inasmuch as this is the most common cause of pericardial inflammation. And, remember, that in some of these cases the pericarditis is not only the first sign of rheumatic attack, but in some instances it may be the only sign, as was the case with a patient you saw before.

Pericarditis is one of the diseases for which the older writers were very much in the habit of giving mercury. It was thought that mercury was especially valuable as a means of preventing fibrous exudation and of absorbing it when it had occurred, so that in the time of Dr. Latham, and even in the time of Dr. Watson, the utility of small doses of mercury pushed to the point of ptyalism was considered as pretty well established. When mercury was banished from the pharmacopœia almost entirely, as doctors lost faith in its power over inflammations, it ceased to be used in this disease, and I think that very few, of late years, are in the habit of using mercury in pericarditis, or of treating it in any other way than they would treat rheumatism, by antiphlogistic remedies and by local counter irritation. The location of the disease is such as to lead one to expect a good deal from counter irritation, as by cupping and by blistering the præcordial region. Most of these cases, therefore, are treated by counter irritants, in the shape of blisters, cupping, etc., and for the rest, they are treated on general principles, according to the morbid condition with which they are supposed to be complicated. I have told you that pericarditis arises under various circumstances. It occurs, for example, in the course of some of the essential fevers. It is a complication, not infrequently, of scarlet fever; it is a complication of typhoid fever sometimes; it is a complication of rheumatism more frequently than of any other disease; and it is one of the issues of that condition of the blood which arises from protracted disease of the kidneys. It is one, that is to say,

of the issues of the uræmic state, and not a very uncommon mode of termination in chronic renal disease. It also arises as a result of pyæmia.

Now, the treatment of pericarditis, so far as medicines are concerned, is based upon the condition which accompanies it. If it complicates a case of scarlet fever your treatment will hardly depart from the treatment which you had inaugurated for that disease. You might resort to counter irritation, but I do not think there is any special medication which you would resort to under these circumstances other than the medication which is appropriate for the disease with which it occurs. Then, again, where it arises as a complication of rheumatic fever, it has been thought of late years that the treatment which was indicated for the arthritic disease was the most appropriate for the pericardial complication. And so with the other conditions which are complicated by this disease. The idea that mercury has any specific effect in preventing the occurrence of excessive fibrous exudation, or in causing its absorption after it has occurred, is, I think, not tenable, and very few cases nowadays are subjected to the mercurial treatment.

The chances of recovery from pericarditis depend upon the condition under which it arises. In the rheumatic form it is almost invariably followed by a successful result. That is to say, it is very rarely a fatal malady where it is rheumatic in its origin. It is in pyæmia and chronic Bright's disease one of the modes of termination. In scarlet fever, where it seems to be associated most frequently with the acute form of Bright's disease, it is a very serious complication, though not necessarily fatal.

Communications.

RŒTHELN, OR GERMAN MEASLES.

BY E. R. STONE, M.D.,

Of Philadelphia.

Read before the Northern Medical Association, of Philadelphia.

If I may be allowed a somewhat paradoxical expression, I would say, at the outset of these remarks, that the chief importance of rœtheln rests in the knowledge of the fact that it is not important at all. While the future welfare of our patients is in no wise jeopardized by an attack of this disease, we, as all-wise physicians, are expected to recognize all sorts of disease, even the most trivial, and form a diagnosis on sight. It is for the purpose of refreshing our memories on some of the prominent features of rœtheln, and to start a discussion upon it, that I have ventured upon these remarks.

It has been only of late years that observers have admitted the existence of an eruptive fever (separate and distinct), but having some likeness to scarlet fever, and especially to measles. Indeed, I presume that many still refuse it a place as a distinct disease, holding some one of the old ideas prevailing years ago. The chaos of conflicting opinions and theories is well reflected in the various names which have been given the disease from time to time. Thus we find it called "roseola" by the English, "rubeola" by the Germans, or "rœtheln," and German measles or bastard measles by those whose clumsy tongues fear to attempt the German diphthongs. It will be interesting to look for a moment at the history of the disease, and for this purpose, I will draw largely upon the article in Ziemssen's Cyclopedia.

More than a century ago, English and French observers described an exanthem similar to, but with many points dissimilar to measles and scarlet fever. This received the name of "roseola," and was soon afterward described by the Germans under the name of "rubeola." This latter name was particularly unfortunate, because in English speaking countries, at least, this name had already been appropriated for real measles. Perhaps this latter circumstance assisted in creating confusion as to the nature of the disease, for we find many competent men confounding rubeola with measles and scarlet fever, and even teaching that an attack of it would protect from the more dangerous exanthem.

Even as late as the middle of the present century many looked upon it as anomalous measles or scarlet fever, and some even brought forward figures to show that it destroyed more lives than either of the more common fevers.

Others allowed a "certain individuality" to the disease, as a hybrid or cross between measles and scarlet fever. Others, like Willan, Hebra and West, refused to give it place as a specific disease, regarding those cases which could not be classed as anomalous measles or scarlet fever, as simple roseola from ordinary causes. Later observers have, however, discarded all of these views, and have been led to look upon it as a separate disease, chiefly because it presents several features of its own, and especially because it has been observed to occur in persons who have already had measles and scarlet fever, and also that it carries with it no immunity from the latter diseases. These facts, I think, give a quietus to all theories which seek to class rœtheln

with measles and scarlet fever, while its epidemic nature and undoubted contagiousness will not harmonize with the idea of a non-specific disorder.

If, then, we assign to rötheln a place of its own in the list of eruptive fevers, we have a contagious, self protecting disease of slight severity and short duration, with an eruption which, in the majority of cases, has a decided resemblance to that of measles, although it is said in some cases to be more like that of scarlet fever. But in searching the literature of the subject I have not been able to find the record of any cases of a scarlatina-like eruption. They have all been a measly rash, and the number of cases which I have seen in the last few months have all been of the latter character. Rötheln has a decided epidemic tendency, and several epidemics of it have been carefully observed and described. It is said to have an incubative period of about fourteen days, although a sufficient number of facts are wanting to substantiate this point. It has an undoubted preference for children and young adults, and we have no record of second attacks. The onset of the disease is usually quite sudden, and there is no period of invasion, such as is so well recognized in ordinary measles. The eruption appears coincident with, or very shortly after, the development of a slight catarrhal condition of the eyes and naso pharyngeal mucous membrane. In many cases there is absolutely no fever, even at the invasion of the disease, a fact which I have had several opportunities of verifying. In other cases there is a slight rise in temperature, which is often accompanied at first with some chilliness. It is also stated that the glands of the neck are often somewhat swollen. I have noticed in several cases swelling and tenderness of one or two post-auricular glands. The eruption of rötheln deserves careful study to distinguish it from that of measles. It first appears on the face as small, elevated, rose-colored points, about the size of pin-heads; these appear in round or oval groups, not generally confluent, smaller than those of measles and not crescentic. The eruption spreads rapidly from the face, consuming from one to two days in covering the surface of the body. It remains but a few hours well-marked, and has already begun to fade on the face before it has reached the feet. In the majority of cases no desquamation can be detected. I have noticed, however, a slight staining of the delicate skin of the face, lasting for two or three days after the disappearance of the rash. There seems to be no disorder of the digestive organs, and no tendency to bronchitis or kidney involvement. Indeed, if, as often happens, there is no fever, the patient is not considered sick enough to keep the bed. I have always noticed some congestion of the throat and slight swelling of the tonsils, but very little of the coryza usual in measles. In the case of a young lady, the throat trouble remained obstinate until some astringent application dissipated it. It will be remarked that this account of symptoms has many points of likeness to the features of common measles, and, undoubtedly, a sporadic case of rötheln might easily be mistaken for an anomalous case of that disease; but a succession of similar cases of this kind, and none of ordinary measles, would decide in favor of rötheln, for measles masked and ill-defined in one will almost certainly show itself plainly in another patient exposed to the contagious principle.

Allow me to emphasize briefly the points of importance in differential diagnosis. In measles there is a well-marked prodromal stage of catarrh; in rötheln the eruption appears at the same time as the catarrh. The papules of measles are larger and more red, and arranged in a crescentic form; those of rötheln, smaller, paler, and grouped in round or oval spots. The fever of measles is marked and persistent until the fading of the eruption; of rötheln absent, or slight, subsiding in a few hours. There is well-marked desquamation in one, very little, if any, in the other. The eruption of rötheln disappears in from one to two days, that of measles lasts for four days. The distinction from scarlet fever is plain, for, at least at this time, rötheln has no marked similarity to it.

The clinical history of the disease in a household where I had opportunities of studying it will be interesting in this connection. It was first noticed in the latter part of November, affecting a boy aged twelve years, who had the eruption marked on the face, trunk, and arms, but scarcely visible at all on the lower extremities. He was said to have had slight fever at the onset, but none was found on my visit, three or four hours after. The tongue was slightly coated, eyes red, and some difficulty in swallowing, due to some redness and swelling of the mucous membrane; a post-auricular gland on the right side was enlarged, other lymphatics apparently normal. I had previously attended him with undoubted measles, and by one of those happy accidents of inspiration, I blundered upon the diagnosis of German measles, the correctness of which I think was proved by subsequent events. In between two or three weeks a little

girl aged five years was attacked with almost identical symptoms, the only difference being that the rash was even less plentiful than in the first case. Cases three and four occurred in about one week after the second and four after the first. The disease this time attacked a light-colored woman of about thirty, and her son of ten years. In them there was no fever or indisposition sufficient to put them to bed. Finally, three others in the family were seized during the last week in January. These were all females, æt. respectively fourteen, twenty-four and twenty-nine. The last mentioned, a married lady and mother of Case two, was much more ill than any of the others. The eruption came out confluent on the face, which, with the injection of the eyes, gave her a decidedly bloated appearance. And the small round groups of papules on the wrists and neck, at first glance, looked uncomfortably like smallpox, a similarity which would not, however, stand the test of close examination. Tongue white, throat considerably inflamed. The thermometer marked one hundred and one degrees in axilla, and there was premature menstruation. In less than twenty-four hours the rash had covered the whole surface and was beginning to fade on the face; temperature ninety-nine and a half. At forty-eight hours a mere trace of eruption was all that remained, and the fever had entirely disappeared. During the height of the disease painful and swollen glands were noticed behind each ear. In this case, in spite of the severity of the skin involvement, no desquamation could be detected. The only abnormal sensation complained of in the skin was a sense of tension and slight burning.

The history of these cases is important as evidence of the contagiousness of the disease Whence the first case came I am quite in the dark, without it can be charged to that alleged disseminator of disease, the public school. That this first case infected the others I feel convinced, in spite of the opinion of a medical friend, who would explain them all on the theory of roseola from ordinary causes. This view, it seems to me, is untenable, because the eruption was not like an ordinary roseola, and it is surely charging too much to the account of that much abused organ, the stomach, to suppose a skin eruption would follow indigestion successively during two months, in seven members of one household, and that without the slightest evidence of indigestion, except the rash. Another fact is noteworthy—the disease attacked all the children and young adults living in the house, thus consuming all the material which we are taught it is wont to feed upon. No efforts at isolation were attempted after the trifling nature of the disease was explained, so that abundant opportunity was afforded for its spread throughout the family.

TRAUMATIC TETANUS—RECOVERY.

BY M. C. BUIDRIDGE, M.D.,

Of Huntsville, Ala.

Jesse Jordan, colored, laborer, aged about 25, while cleaning the saws of a cotton gin when in motion, November 19th, received on the dorsal aspect of the forearm a severe wound, which was inflicted by four saws, cutting as many parallel lines, from one-fourth to one-half of an inch in depth, beginning at a point two inches below the elbow, and terminating at the metacarpo-phalangeal articulation. Two of the extensor tendons were divided and the third metacarpal bone well nigh severed. Intense pain and considerable hemorrhage were present. The wound was thoroughly cleansed with cold water, the incisions were dusted with salicylic acid, the divided tissues were brought as nearly together as possible by adhesive plaster, then dressed with carbolized oakum, over which a thin roller was loosely applied. A full dose of opium was then administered, and instructions given to continue the opiate as often as necessary to relieve pain and promote sleep. Patient reported at my office on the 22d, being the third day after the accident. The dressings were removed, the wound thoroughly cleansed, when salicylic acid, adhesive plaster, carbolized oakum and roller were applied, as in the former dressing.

25th. Wound dry and hot, but little suppuration. Cleansed with warm water, and changed the salicylic acid for Peruvian balsam, which was freely applied with oakum and plaster as before.

28th. Wound very much improved, suppuration and granulation going on well. Continued treatment.

30th. Wound nearly closed throughout from above downward to a spot on the dorsum of the hand, spot not larger than half a dollar. Ordered a continuation of the balsam and oakum dressing until cured.

Dec. 15th. I was summoned to see my patient, and was informed by the messenger that patient thought he had taken cold; his side pained him, could not bend his neck, nor could he swallow as usual.

I at once suspected trismus, and advised the messenger to have another doctor to see the patient, as I was engaged for the night, and could

not see him for several hours at least. Failing to secure the services of a physician, I prescribed chloral hydrate in thirty-grain doses, to be given in syrup lemon, every two hours, until pain was relieved and sleep induced.

December 16th. On visiting my patient I found him suffering from tonic spasm of the post-cervical muscles and muscles of the back; could not bend his body nor open his mouth sufficiently to protrude the tongue, nor could he swallow solid food, an effort to do so would instantly provoke a convulsion. The wound, on examination, I found healed entirely, except a small spot immediately over the third metacarpal bone. The wound had not given him any trouble for more than two weeks; his bowels were confined, had not been opened for three or four days; pulse about natural; temperature normal; urine normal. He complained of periodical paroxysms of pain and spasm recurring at intervals of twenty or thirty minutes. The pain was referable to the epigastric region, and extending to the back.

On inquiring I found he had taken the chloral as directed, during the afternoon and until midnight, when he felt relieved and discontinued the medicine. I then gave twenty grains of calomel and directed a clyster to be given in three hours. Ordered patient to be placed into a water bath as warm as he could bear, and kept in the same for four or five hours, frequently adding warm water:—

℞	Chloral hydrate,	grs. xv	
	Potassi bromidi,	grs. xv	
	Fl. ext. Calabar bean,	gtts. v.	M.

in simple syrup every two hours, to be continued until spasms and pain were relieved.

17th. Patient rested much better during the afternoon and evening of the previous day, but did not rest well during the latter part of the night. Bowels had moved freely. Pulse 100; temperature 99°; urine scanty. He had not taken any nourishment save a small quantity of sweet milk. Continued treatment, with positive instructions to keep up the use of the medicine every two hours until its full effects should be realized.

18th. Patient slept about three or four hours during the afternoon, and about the same during the night. Pulse normal in frequency, but not so full. Temperature 99°; urine not so scanty; has taken beef tea and milk punch. Continued treatment, but did not require the bath to be taken so often.

19th. His condition much better, though opisthotonic spasms continue, with paroxysms of pain every two or three hours. Has slept some during the night. Took medicine regularly until midnight, and took one bath. Calls for chicken broth and milk punch. Continued treatment.

20th. He is very much better, though sudden noise or surprise will provoke a spasm, well marked, but short and slight. Discontinued the bath. Ordered beef tea and milk punch to be freely given. ℞. Bromidia, ʒj, prepared by Battle & Co., St. Louis, with the usual amount of Calabar bean; dose three or four times daily, according to symptoms, with instruction to keep patient quiet and warm. Treatment continued until the 25th, when it was discontinued entirely, and patient discharged cured.

The points of special interest in this case are, first, the length of time which elapsed after the injury was received until the development of tetanus, the time being twenty-six days.

Secondly, the duration of the tetanic seizure, that being about twenty days. Thirdly, the large amount of chloral hydrate and potassii bromidi which was taken, about one and one half ounces of the former and one ounce of the latter, together with not less than one-half ounce fluid extract Calabar bean. Most of this medicine was taken during the first five days.

Lastly, the marked benefit which was derived from the use of the hot baths. This was, in my opinion, incalculable. The bath did not only have a decided relaxing effect, but in a marked degree tranquilized the nervous system, thereby assisting the Calabar bean to relax the tonic muscular rigidity, while at the same time it assisted the chloral and bromide in controlling the nervous system.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

SERVICE OF DR. JAMES H. HUTCHINSON.

Reported by Dr. George F. Souwers.

A Case of Myelitis Following Caries of the Spine.

Gentlemen:—The patient I shall bring before you this morning is S. W., aged 34, a machinist by trade, who was admitted into the hospital on February 9th of the present year. His family history shows that his father died of dropsy, his mother of some injury the nature of which he does not know, and all his brothers and sisters are living and in good health. Three and a half years ago he had an attack of quotidian ague, which lasted for two months, and which has not since returned. Before this, however, he noticed that when he sneezed or drew a full breath he could feel a sharp pain in the region of the stomach. Lately these pains have become more severe and

are now caused frequently by the act of coughing. About three years ago, after having been working in the rain and in consequence having got thoroughly wet, he was seized with a sharp burning pain in the small of the back (low down in the lumbar region), which lasted about a week. From that time he was subject to recurring attacks of pain, which not only gradually increased in severity but also in frequency and duration, until early in the summer of 1879, when the attacks became less severe, and after a time ceased to recur. During one of these attacks of pain, while he was having his back rubbed, it was noticed for the first time that there was a curvature of the spinal column, low down in the dorsal region. It was very slight at that time, but has since gradually become more marked. He has never suffered pain in the curvature itself, all of his pain being at first referred to the small of the back.

After the cessation of these lumbar pains, in August, 1879, he felt almost perfectly well, until the following January (about one year ago), when he began to suffer from sharp shooting pains in the legs, and noticed that they would feel tired after a slight exertion; this feeling of fatigue was shortly followed by one of weakness, and he soon afterward observed that he dragged his toes in walking. This caused him to stumble frequently. The loss of power gradually increased, and during last summer became associated with a decided diminution of sensation in the same parts. Last September retention of urine and constipation were added to the other symptoms, but during the past two months the retention of urine has given place to incontinence of urine. In December last he had a recurrence of the pain in the back, and for several weeks past he has suffered from spasmodic twitchings of the muscles of the lower extremities, which gives rise to severe pain, especially at night. He has never had any feeling of constriction around the body, in other words, he has not suffered from the "girdle sensation." So far as we can discover, he has never received a blow or other injury of the back, but he thinks he has frequently strained it in lifting heavy weights. He admits that he has had an attack of gonorrhœa, but denies ever having had syphilis, and, moreover, does not present any evidence of having suffered from specific disease. I accept his testimony on this point, as he appears to be a truthful man. Until last fall he was able to walk on crutches, but at that time the twitchings of the muscles of the legs became so violent, and was so much increased whenever his feet touched the ground, that he was obliged to give up all attempts at walking. Indeed, he says that he was sometimes thrown down by the violence of these muscular contractions. About two months ago the paralysis became complete, and he has since been confined, most of the time, to his bed. Headache has been present only for the last two weeks. His appetite has always been good.

I have culled the foregoing facts for you, gentlemen, from the statements made by the patient, and entered, upon his admission, into the hospital register. On referring to the notes of the resident physician, I find that upon admission the patient was free from fever and anæmic, that the bowels were constipated, and that, though able to tell when he was about to have a passage, yet he was unable to control it; that incontinence of urine was still present; that the tongue was clean and the appetite good.

He has a marked posterior curvature in the neighborhood of the tenth dorsal vertebra; both legs are completely paralyzed, the muscles being quite rigid and somewhat wasted. The patella reflex and ankle clonus are well marked, especially on the left side. The urine is slightly albuminous, which is probably owing to its containing a good deal of pus.

We have now the history of the case, and so our next step must be the consideration seriatim of all the issues involved. On examining him I find a curvature below the middle of the dorsal region, but he insists that the pain has always been lower down than this; in fact, there is not much tenderness even on forcible pressure over the curvature. Upon the back there are a few points of superficial ulceration, which shows that there is a tendency to the formation of bed-sores. This, as you are aware, is not an uncommon occurrence in certain spinal affections, and indicates that the nutrition of the parts is in a depressed condition.

On examining his legs we find them flexed, and, as you see, requiring the exercise of considerable force on the part of my assistants to straighten them. The slight movement of the lower extremities which the patient is able to produce is due entirely to a feeble contraction of some of the muscles in the region of the hips. But while, as I show you, reflex action is enormously increased, he is unable to move even his toes, much less to raise his feet from the bed. A pin thrust deeply into the skin of any part of his legs always gives rise to the sensation of heat, which is at times very painful to him. He does not feel the same pin if the skin of the leg or thigh is lightly touched with it, but normal sensation is found to exist above the level of the umbilicus.

If the feet are forcibly and rapidly flexed, decided convulsive movements of the muscles of the calf are produced. This is technically known as the ankle-clonus, and is more marked in the left side. If the patella of the same side is drawn down rapidly, the quadriceps femoris is in the same way thrown into clonic spasms. The patella tendon reflex is also increased. This is the name given to the contraction of the same muscle produced by striking the tendon of the patella, when the leg is flexed and allowed to hang loosely over the arm of the operator, or crossed over the opposite knee.

I have alluded to the fact that after retention of urine had existed for some time it was replaced by incontinence.

It frequently happens in these cases that the incontinence is only apparent, and that the condition really present is retention, the over-distended bladder relieving itself by a constant dribbling from the penis, just as it does occasionally in typhoid or other fevers. It is not an unusual circumstance for the nurse to assure the physician, in such cases, that the patient has passed his water freely, and to point to the soiled bed in confirmation of his statement. Yet, on

examination, the bladder may be found greatly distended. Consequently, you must, in all spinal and febrile affections, watch closely the condition of this organ. In this case I have satisfied myself that retention does not exist.

The upper portion of the body seems to be free from any nervous trouble, the grasp of the hand being almost as strong as in health. All the symptoms, therefore, point unmistakably to disease of the cord seated at or near the position of the curvature of the spine. Further, you will recollect that the patient insists that the first symptom he noticed was pain on sneezing, referred to the region of the stomach and umbilicus. His pain was sometimes caused even by a deeply drawn breath. It undoubtedly indicated the existence of serious disease of the vertebræ, and of commencing disease of the cord or of its membranes. It was a warning which, unhappily for the patient, was unheeded, for at that time proper treatment would have prevented, in all human probability, the occurrence of the serious disease of the cord from which he is now suffering. There can be no doubt that in this case the parts first diseased were the lower dorsal vertebræ; that from them the inflammation has extended to the spinal meninges, and that finally the cord has become involved. Pain in the epigastric region is not infrequently one of the first symptoms of caries of the vertebræ, and is probably due to irritation of the posterior roots of the nerves. The pain in the back was unquestionably largely caused by the disease of the vertebræ; but the pain in the legs, which occurred later, was probably chiefly due to spinal meningitis. The twitching of the muscles, the anæsthesia, and the paralysis, we must, of course, refer to implication of the cord itself.

The convulsive twitching of the muscles and their rigidity is one of the most remarkable phenomena of the case. You will rarely see one in which the ankle and the patella clonus and the tendon reflexes are so well marked as in this. These are symptoms which have been recently referred to disease of the lateral columns of the cord. This is, however, a hypothesis merely, supported rather by physiological than pathological researches. The alterations of sensation indicate the existence of disease of the gray matter of the cord. These alterations of sensation are very peculiar, and I will call your attention to them more particularly than I did in the early part of my lecture. A light touch with the finger or a pin the patient does not feel at all anywhere below the level of the umbilicus. If, however, the pin is thrust deeply into the skin of the foot the leg is instantly jerked away with a good deal of force, and he complains of a burning pain. The same effect is produced by a lump of ice, or by heated metal. I have spoken of the force with which the foot is jerked away when a pin is thrust into it, and I shall tell you presently how I was able to make a rough estimate of the amount of this force. These contractions are caused by a much slighter irritation than the insertion of a pin into the flesh. Thus, the weight of the bedclothes resting on the feet and the passage of the fæces are sufficient to cause them. Wishing to prevent them, or at least to moderate their violence, I attached weights to his feet, just as is done in making extension in the treatment of fracture of the thigh. The experiment, however, failed completely, and was soon abandoned, sixteen pounds being raised a considerable distance almost as easily as I could lift them from the floor. There is little wasting of the muscles of the lower extremities, which would seem to indicate that the anterior cornua of the gray matter are not largely involved in the disease.

I have already said that the time for an efficient treatment of this case has been allowed to pass. Unfortunately, the physicians who first saw him mistook the nature of his malady, and addressed their treatment principally to a gastritis which they believed to be present. Is all treatment at the present time, therefore, useless? I think not, for although it would be unreasonable to expect a restoration of power to his legs, yet something may be done to migitate his suffering. We have here, unquestionably, myelitis to contend with, and we should therefore employ those remedies which experience has shown to be useful in this disease. I prescribed for him, upon his admission, large doses of ergot. I cannot see that any material improvement in his condition has followed the administration of this remedy, so I shall, therefore, discontinue it, and order for him twenty grains of iodide of potassium and one eighth of a grain of extract of belladonna three times a day, and shall direct that the dose of the latter drug shall be rapidly increased so as to bring him quickly under its influence.

As you are aware, electricity in its various forms is used in the treatment of almost all forms of paralysis, but in the present case, in which the irritability of the cord is so much increased I believe that it would only do harm, and have, therefore, not had recourse to it even for the purpose of testing the condition of the muscles. I am more in doubt in regard to the propriety of employing another remedy. I mean the plaster jacket of Professor Sayre. Unquestionably the disease has gone too far to allow us to hope much from it; but it might possibly, by causing a diminution of pressure upon the cord, favor the operation of the medicines I have prescribed, and I have therefore determined to resort to it. It is only fair to say that he has already had one applied and that it gave rise to pain and inconvenience rather than to relief from distressing symptoms. This may have been owing, however, more to want of skill in its application than to the remedy itself. The experiment is, I think, worth trying, and if it fails, it will at least do no harm.

Some of you may be inclined to attribute all the patient's symptoms simply to pressure, believing that this is alone, and in the absence of inflammation of the cord, sufficient to produce them. Although the sudden displacement of a vertebra, or the occurrence of an intra-spinal hemorrhage, is at once followed by paralysis, experience has shown that the cord accommodates itself to the more gradually occurring pressure occasioned by caries of the vertebræ, or by an intra-spinal tumor, and that paralysis does not usually occur until these sources of irritation have given rise to myelitis.

Note, March 29.—The plaster jacket was soon

after the delivery of this lecture, applied by Dr. Charles T. Hunter, Surgeon to the Out door Department of the Pennsylvania Hospital. Up to the present time no good results have followed its application, and it will shortly be removed. The patient, perhaps, suffers less pain than when first admitted, but, with this exception, there is little or no improvement in his condition.

Medical Societies.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

The President, Dr. J. B. Walker, in the chair.

Dr. E. R. Stone read a paper upon Rœtheln (see page 482). The Secretary then read a communication from Dr. W. B. Atkinson, who said: The subject is important because so constantly is this disease taken for measles, scarlatina, and even smallpox. The point which I desire particularly to impress is that the diagnosis is made by the *rapid extension* of the eruption from the face and neck over the body and extremities, and its *equally rapid disappearance.*

It is really harmless, never leaving any sequel, rarely requiring treatment. It is highly contagious. The eruption in various cases resembles measles, but without the crescentic appearance, or is efflorescent, like scarlatina.

An additional reason for an early and positive diagnosis is the relief thus afforded to all when the mild nature of the disease is known.

Dr. Wittig said that the treatment of all these slight fevers of childhood was chiefly the relief of symptoms, and that no mistake could be made even though a wrong name should be applied.

Dr. Hess had never before had his attention called to this disease, but now recognized it in two cases now reporting at the dispensary, and which he had thought to be measles in an aberrant form.

Dr. Welsh had seen several cases of the so-called German measles. About a dozen have been sent, this winter, to the Municipal Hospital, as cases of smallpox. The eruption resembles that of ordinary measles, except it lacks the crescentic form of the patches; had seen a similar eruption follow vaccination, especially when the *bovine* virus had been used. He had also seen such an eruption immediately precede that of variola. There is always a doubt about the diagnosis. Had seen nothing to show its contagiousness, no second case appearing in the families under his care. No particular treatment required.

Dr. Montgomery reported three cases in which the eruption covered the whole body, being confluent in places; where discrete the patches were circular. None of them were sick, except the alarm caused by the appearance of the skin. They had not been vaccinated, and had all had the measles previously.

Dr. Beates had seen eleven cases this winter, two of which were attacked seven and nine days, respectively, from the time of their exposure. Two of them had measles previously. He had noticed no coryza or fever, but had observed an enlargement of a post-auricular gland, and slight inflammation in the throat. He understands that there is an epidemic now in progress in the Girls' Normal School of this city.

Dr. Heilman reported one case that he had attended in measles one year before. He understood that the disease spread through the family, but no physician was called.

Dr. Walker had seen one case upon a colored person, where the eruption so resembled smallpox in its first stage that he refused to give a diagnosis at the first visit; it disappeared, however, in two days.

Dr. Stone said he was very glad to hear many of the members say they had recently seen cases of rötheln, because so many others had cast a doubt upon the existence of the disease. For diagnosis the main points, he thought, were the absence of prodromes and of coryza; the rapid spreading and equally rapid fading of the eruption. There are no complications.

Periscope.

Treatment of Delirium Tremens.

Dr. Chancellor gives his treatment in the St. Louis *Medical and Surgical Journal*, as follows:

In recommending the plan of treatment to be described, the results for the past years clearly prove that no method can yield a more successful issue. I am aware that I do not agree with some of my professional friends, for whom I entertain the highest respect, but the evidence of its effects has been of a nature which I cannot refuse to admit and adopt. I lay no claim, of course, to originality in advising a treatment which has been often used, for the disease tends to a natural recovery, and it may be possible that other methods prove equally successful. In estimating the value of remedies in delirium tremens, we should recognize the fact that slight cases get well spontaneously, or a simple palliative treatment may diminish the suffering of a patient. First, we should place the patient in a dark, quiet room, well ventilated, and exclude all but the attendant nurses; when the disease comes on during a debauch, or shortly after, and there is reason to believe the stomach contains alcoholic or malt fluids, an emetic should be prescribed; the best for this purpose is warm water, mustard or ipecac, or if necessary, the stomach pump may be used. Emetics, as they are generally supposed to act chiefly upon the stomach, do not produce by their local action the most beneficial effects; it is their general influence that the lan-

guor and relaxation which follows emesis calms the nervous agitation and disposes to a healthy sleep; if the emetic has not acted on the bowels, which it often does, a brisk purgative may be given (though not advisable in all cases), as it is a safe way of getting rid of the alcohol, which impedes the absorption of food. The patient is thus put to bed in a quiet room, under the care of a skillful nurse, who gives by direction—

R.	Tinct. digitalis,	℥ ss.	℥ vj
	Tinct. capsici,	℥ ij	
	Spt. ætheris comp.,	℥ ss	
	Aq. camph., q.s ad.	℥ ij.	M.

Sig.—Two tablespoonfuls well diluted with water, at intervals of three or four hours.

Should the first dose not pacify the patient, a second should be given, but seldom is it necessary to administer a third, but if it be required, give only one tablespoonful; the patient will now rest quietly for eight or ten hours. This should be followed by nutritive food, milk, soups, beef tea, eggs; but if there is much sickness or nausea, an effervescing mixture, Horsford's acid phosphate, soda water, milk with lime water, may be given; if patient refuses food, nutrient enemata must be employed. Stimulants now become absolutely necessary, but many physicians will hesitate, on moral considerations, from a dread of either seeming to give countenance to the habit of spirit drinking, or from fear of adding "fuel to the fire." It is true, that the majority of cases of delirium tremens do not require stimulants, for a variety of methods will cure the disease, or it will, in a greater number of cases, get well itself. Stimulants are absolutely necessary if the patient is a habitual drunkard, old or feeble, or if there are signs of adynamia. The most serviceable and popular are brandy, porter, cider, etc., which should be administered as the symptoms require it, or the judgment of the physician may dictate.

Ocular Symptoms in Different Diseases.

Dr. Gorecki, as quoted in the Glasgow *Medical Journal*, has tabulated his views as follows:—

Blepharoptosis, or the falling of the upper eyelid, indicates paralysis, complete or incomplete, of the third pair.

Lagophthalmos, or inability to close completely the palpebral fissure, is a sign of facial hemiplegia, idiopathic or a symptom of cerebral disease.

Strabismus occurring suddenly, and accompanied by diplopia, is most frequently the result of some cerebral affection.

Xanthelasma (a yellow lamina sometimes met with in the skin) of the eyelids, occurs in certain alterations of the liver.

Sub-conjunctival ecchymoses are frequent in whooping-cough, and may sometimes, at the beginning of the complaint, clear up a difficult diagnosis.

Redness of the conjunctiva, watering of the eye, etc., indicate in the child the outbreak of some eruptive fever, particularly measles. The prognosis is favorable if the tears come when the child cries, but fatal if the secretion of the tears is arrested.

Spots on the cornea are often the indication of a strumous constitution.

Dilatation of the pupil, or mydriasis, indicates excessive fatigue, the existence of intestinal worms, meningitis in the second stage, or a true amaurosis. The dilatation is most frequently connected with atrophy of the optic nerve. It is seen also during an attack of epilepsy, on coming out of chloroform, after belladonna poisoning, etc.

Unequal dilatation of the two pupils points to the onset of general progressive paralysis.

Contraction of the pupil is one of the early symptoms of *tabes dorsalis*. It is met with also at the beginning of meningitis, in opium poisoning, and in the first stage of chloral poisoning.

Deformation of the pupil, particularly after the injection of atropine, indicates an old iritis, in nine cases out of ten, of syphilitic origin, if not depending on some disease of the neighboring parts.

Cataract in subjects under say forty or fifty, is frequently of diabetic origin, and constitutes soft cataract.

Finally, the ophthalmoscope enables us to recognize the retinitis of albuminuria in Bright's disease, of simple polyuria, and sometimes in the case of women during pregnancy. Retinal hemorrhages, œdema of the retina, and embolism of its central artery, are sometimes met with in organic affections of the heart. Optic neuritis and perineuritis and atrophy of the disc are symptoms of syphilis, or of tumors in the neighborhood of the cerebellum or the *corpora quadrigemina*.

On Herpes Facialis.

The following extract is from a lecture by Dr. J. M. Finny, published in the *Medical Press and Circular*:—

Herpes facialis—a better name than *herpes labialis*—is met with most usually on the lips, at the muco-cutaneous juncture; but it occurs also on cheeks, ears, and nose. Though an accompaniment of an ordinary cold or dyspeptic attack, *herpes facialis* is present in pneumonia, cerebro-spinal, intermittent, and scarlet fevers. During the present session you have seen it in both scarlet fever and pneumonia, and you will recollect the different significance which may be attributed to it in these two diseases. In the latter, so usually do the patients who present it recover that some authorities consider it a most favorable prognostic; while in scarlet fever it is an omen of a severe type, in which nasal discharges, arthritic complications, and a prolonged fever may be expected. The late Dr. Stokes used to lay down, as a maxim worthy of note, that a vesicular complication of fever was ever one of serious import.

The most extensive case of facial herpes I ever met with occurred in a patient, aged sixty-six, who was admitted to this hospital in 1879, for pneumonia, as the whole of his right cheek, extending from the zygomatic arch to the nose was one mass of herpetic clusters, which became confluent. He made a rapid and good recovery. Notwithstanding the frequency of the favorable issue of pneumonia attended by herpes, I would not have you lay too much stress upon the value attaching to this symptomatic rash, inasmuch as most cases of sthenic pneumonia have a tendency

to recovery, and many cases in which herpetic rashes are absent do equally well.

The ordinary cases of facial herpes present no difficulties of diagnosis, but you should remember it may attack the mucous membrane of the mouth and palate. Should it be confined to these places, you may find some difficulty in recognizing the disease.

Within the last couple of months I came across a rather puzzling case of herpes, in consultation with Dr. William Lane, in the person of a well-known clergyman of this city. The whole soft palate, uvula, and arches of the palate were studded with vesicles standing on a reddened base. At first sight, scarlatina or diphtheritic inflammation passed through my mind; but the absence of the characteristics of those diseases, and the presence of a most copious vesicular eruption on the alæ and dorsum nasi, the upper lip, and the adjoining surfaces of the cheeks and chin, made the diagnosis easy.

Constitution of Human Milk.

F. Hoppe Seyler's "*Zeitschrift für Physiologische Chemie*" contains a valuable paper by Dr. P. Radenhausen, on human milk as compared with the milk of the cow, quoted in the *Chemist and Druggist.*

The author, after alluding to the importance of the subject from the point of national economy, by showing that the great mortality of infants under one year of age is chiefly owing to the substitution of cow's milk for that of the mother, especially in Paris, where the mortality of infants of the age mentioned has been as high as eighty-five to ninety-two per cent. of the births, gives the following account of his investigations:—

HUMAN MILK.

Specific Gravity.—The specific gravity of human milk varies according to the quantity drawn, between 1.028 and 1.034. Upon allowing the milk to collect for some hours in the mammary glands, the first portion drawn shows a higher specific gravity with little fatty matter, the further portions a constantly decreasing specific gravity with increase of fatty matter.

Milk Globules.—The milk globules are for the most part free from fatty globules.

Chemical Nature.—Human milk contains no caseine, but a kind of albumen with a small quantity of proteine and peptone, as found in blood. Human milk is alkaline, and contains far more sugar in proportion to the albumen than cow's milk.

ESSENTIAL DIFFERENCES BETWEEN HUMAN AND COW'S MILK.

Human milk is always alkaline, cow's milk nearly always a little acid and easily turns sour, which human milk does not so readily do. Cow's milk contains a larger proportion of proteine than human milk, and more albumen in proportion to saccharine matter, which is the converse of human milk.

A glance at the differences between human and cow's milk shows how well nature has provided for both man and beast. The young calf, which very soon skips about after parturition, requires more albumen and less sugar than the young child, whose tender stomach requires a milk which will not easily turn sour, which contains less albumen and more calorific matter, which it then actually finds in the greater proportion of sugar.

The author hopes that a due consideration of the facts he has here brought to light will enable the chemist to propose a fit substitute for human milk for children that cannot be nursed by their mothers or wet nurses.

The Salicylic Treatment of Typhoid.

Mr. Tomkins reports, in the *Lancet*, that he has tried, in the Manchester Fever Hospital, with some success, the treatment of typhoid fever with sodium salicylate. He says:—

The number that I have treated with salicylate up to June, 1880, is forty-six, twenty-eight males and eighteen females, varying in age from seven to fifty-six years, the larger proportion being between fourteen years and thirty five. They represent only the more serious cases received into this hospital, and are about one-third of the whole number admitted during the time over which the treatment extends. In no case was the soda given when the temperature in the axilla was below 102°. The general treatment, in addition to the special, may be summed up thus: perfect rest, milk diet, with small quantities of beef tea, acid and opium when diarrhœa is excessive, acetate of lead or turpentine, with iced injections, for hemorrhage. Alcohol was never given unless the state of the circulation decidedly demanded it, except, in the convalescent stages of some few cases, in the form of wine. It should be noted that in the whole of these the temperature was taken every two or every three hours, night and day, while the salicylate treatment was being pursued, so that its effect, hour by hour, could be distinctly watched.

The routine practice has been this: As soon as it was certain that there was a continuous temperature of more than 102° in the axilla, fifteen to twenty grains of the soda were given every two hours. This, after about six doses, usually reduced the temperature two to three degrees; if not, the same dose was continued a few more hours until it had done so, this seldom exceeding twenty-four hours from the commencement. The dose was then diminished one-half, and given every two or three hours, increasing it through the day, if there was much tendency to exacerbation towards night-time. This was carried on for a period varying from three or four to nine or ten days, seldom exceeding the latter time, when the temperature would usually be fairly normal, with a little inclination to an evening rise, in many cases, for a few days after the salicylate was entirely discontinued. In most of the cases the usual physiological effects were observed, and in several alcohol was freely administered with the soda, in the form of brandy, whenever the pulse was feeble or the weakened action of the heart appeared to be becoming dangerous.

Reviews and Book Notices

BOOK NOTICES.

Hydrophobia. By Horatio R. Bigelow, M.D. etc. Philadelphia: D. G. Brinton, No. 115 South Seventh St., 1881. 1 vol., pp. 154. Price $1.00.

Of all the diseases to which modern communities are liable, there is, probably, none with greater terrors than that which this volume treats of. The fearful suffering and the generally accepted absolute hopelessness of the attack make it appalling in the highest degree. It is, moreover, widely prevalent, and there is hardly a village in our land but that some time during the year it is not thrilled by the fearful cry "Mad Dog!" For centuries it has been the *opprobrium medicorum*, and the latest investigations of its pathology and treatment, the latest advice as to its prophylaxis and prevention, are far from being either satisfactory or unanimous.

This is not attributable to a lack of study of the subject. Dr. Bigelow tells us that the library of the Army Medical Museum at Washington, alone, contains over *three thousand* monographs, treatises and articles bearing upon it. Being a resident of Washington himself, Dr. Bigelow has enjoyed these exceptional advantages to familiarize himself with the labors of his predecessors, and his monograph is a scholarly and masterly exposition of all that is known on the subject. His abilities as a linguist, as well as his thorough medical knowledge, are conspicuous in every chapter.

The first two chapters are occupied with the nomenclature and history of the disease. It appears always to have been rare in Syria, as, from contemporary travelers, it is said to be at the present day. No definite reference to it is made in the Old Testament, but nevertheless its antiquity is undoubted.

The earliest distinct mention of the disease occurs in a Hindoo medical work of great antiquity, dating probably as far back as nine or ten centuries before Christ, written by a renowned physician named Susruta. It is observed therein that when dogs, jackals, foxes, wolves, bears or tigers become rabid, they foam at the mouth, which remains open, and from which flows saliva; their tails hang down; they do not hear or see well; they snap at and bite one another, and thus communicate the same malady. The symptoms of hydrophobia in human beings who have been bitten are likewise detailed briefly, and are said to terminate in convulsions and death.

Homer and Hippocrates appear to have known it, and Aristotle certainly did; the physicians Galen and Celsus have considerable to say about its treatment. It appears at certain times, under conditions not easily determinable, to have prevailed in an actually epidemic form. One of the most extraordinary of these epidemics was that which occurred in Peru in 1803-4, which Dr. Bigelow describes from a contemporary account:

The disease became general among quadrupeds, attacking them indiscriminately, but fixing itself especially upon dogs. The dogs exhibited the ordinary appearances of the affection. The cats ran about with hair erect. The horses and asses were arrayed against each other. The cattle leaped furiously, and engaged in hostile encounters. The disease, engendered, as the professor believed, by atmospheric conditions, was subsequently propagated by specific contagion, spreading into the interior of the country. It proved fatal to many of the inhabitants of Arequipa and Ica, carrying off forty-two persons in the latter town alone. In one instance, twelve fell victims out of fourteen bitten by a single dog. The largest number of deaths occurred in from twelve to ninety days after the bite. The affection would, therefore, appear to have been of a more virulent character than usual. It is likewise related that a number of slaves upon a sugar plantation contracted the disease by feeding upon the beef of rabid cattle, a statement which we can hardly accept as true.

The pathology and morbid anatomy of the disease are treated with fullness. The author states his dissent from Dr. Hammond's researches and opinions, and reaches the conclusion that the primary exciting factor of the disease is a "blood ferment," of a nature to inhibit the functions of the oxygen carriers of the blood, altering the red corpuscles, and interfering with the integrity of the blood plasma. Speaking of the pathological appearances recorded by Hammond and others, he says:—

The conclusion, therefore, seems irresistible, that the morbid changes noted are not *essential* and *primary* factors in developing the train of symptoms, but are, in all probability, *secondary lesions*, resulting from the terrible disturbance which the disease causes in the functions of the respiratory, vascular and nervous systems. Such phenomena could hardly, therefore, be of any value in determining the pathogeny of the affection, any more than are a thousand and one other morbid changes seen in various organs after death by hydrophobia, and which are well recognized as being merely *consequential* and non-uniform lesions.

The much debated question of incubation and the influence of age, sex and climate, are considered in chapter iv. The writer quotes numerous examples where the period of incubation seems to have extended over a year—even as long as fourteen years—and inclines to adopt Watson's theory, that the virus may become encapsuled in a nodule of lymph and there lie latent for an undetermined period, until some exciting cause shall set it free. Yet he appears

to quote with approval Dr. Dolan's opinion that after a lapse of a year there is a "scientific certainty" of the patient's safety.

Contrary to the general opinion, Dr. Bigelow maintains that mad dogs are about as numerous at one season as at another. The evidence he adduces is exclusively from European authorities, and we cannot but entertain some doubt as to its applicability to this country, where our seasons are so much more extreme than in central Europe. The following are the conclusions of the leading French official investigations on this point.

1. That there is no great difference between the seasons; 2. That the danger from mad dogs in the winter season is about the same as in the heat of summer; 3. That in the spring cases are most frequent, and in the autumn least frequent; 4. That the public opinion which regards winter as free from the curse of hydrophobia, and inculpates summer as causing the disease more than any other season, has no foundation in fact.

"This brings us to a conclusion of great importance, namely, that, so far as sanitary measures and the protection of the people is concerned, at all times and in all seasons we should be equally on our guard, and take efficient measures of protection against dogs. We must, however, observe that although the actual statistics furnish figures indicating an almost parallel number of cases for the seasons of extreme heat and extreme cold, it is due to the greater care in carrying out sanitary measures in summer than in winter."

The chapter on the symptoms, diagnosis and prognosis gives a vivid picture of the early symptoms and progress of a typical case, and the differential signs between such a one and the diseases with which it is possible to confound it, as tetanus, œsophagitis, etc. In prognosis, the author is hopeful, and condemns that despair of the resources of medical science which is too apt to possess the mind of both physician and patient in these cases.

In speaking of treatment, it is divided into the preservative, the curative, and the preventive. Of the innumerable and often absurd means popularly resorted to, or suggested by, writers, the author selects those which appear to be the most scientific, and to have the most evidence in their favor, such as curara, oxygen, the vapor bath, etc. Three chapters are devoted to this most important branch of the subject, but we cannot do justice to their contents by extracts.

The final chapters are entitled "How to recognize a mad dog;" "Emergencies, and how to treat them;" "Curiosities of the literature of hydrophobia," and "The most recent views of the pathology and treatment of hydrophobia."

The space to which this notice has already extended prevents us from continuing our quotations. To those who would make themselves familiar with the character and history, the prevention and the treatment of this dreaded disease, we unhesitatingly recommend this work as, for its compass, the best we have seen on the subject.

An Introduction to Pathology a d Morbid Anatomy. By T. Henry Green, M.D., Lond. Fourth American, from the fifth English edition. Philadelphia: Henry C. Lea's Son & Co., 1881. Cloth, 8vo. pp. 347.

For a brief treatise on pathology—an "introduction" to the subject, as the author properly calls it—this volume has attained a merited popularity on both sides of the ocean. It is judiciously arranged, lucidly composed, and amply illustrated. Without fatiguing the reader with excess of detail, it presents a sufficiency of information on the various degradations of tissue to make their nature and appearance familiar.

Considerable new matter has been added to this edition, and the text throughout has been subjected to a careful revision. Some new wood-cuts have also been added, drawn from the author's microscopical preparations. The cuts are well printed, and number in all 138. The volume is printed and issued with the care characteristic of the well-known firm who publish it.

First Biennial Report of the North Carolina Board of Health, 1879–1880. Raleigh, 1881. pp. 201.

With a wise understanding of the advantages of health to a community, the State of North Carolina created, a few years ago, a Board of Health, the first report of which is before us. The efficient Secretary, Dr. Thomas F. Wood of Wilmington, was active in organizing county boards, subordinate to that of the State. The subjects especially to be investigated were the death rate, medico-legal examinations, drinking water, epidemics, vaccination, abatement of nuisances, etc. All physicians were supplied with blanks to be filled, etc. The results are detailed to a certain extent in the volume before us, in the form of statistical bulletins, etc.

A number of papers are added in the Appendix. The most important of these are a circular on ventilation, drainage, drinking water, and disinfectants, sanitary engineering, by Prof. William Cane, C.E., and the limitation and prevention of diphtheria, by Dr. R. L. Payne.

The start made by the board is a good one, and we have no doubt will be followed by positive and great benefit to the public.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1 60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER-GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

SOME RECENT VIEWS OF LIFE AND ITS FORCES.

Science to-day discards the distinction between Matter and Force, pronouncing it an artificial one, resting on imperfectly understood observations. Motion and Energy are the two factors of the universe.

When we come to apply this general law to the phenomena of Life as exhibited in organized beings, we find that there are two fundamental processes which constitute the primitive forces of living matter. They are, 1. The transformation of kinetic (living or active force) Energy into potential Energy (latent force). 2. The transformation of potential into kinetic Energy. The former may be called an "anenergic," the latter a "katenergic" process.

Plants store up sunlight in the form of potential energy; hence they are chiefly occupied in anenergic processes; but not exclusively, for they also evolve carbonic acid, and thus develop kinetic energy.

Animals, on the other hand, are almost entirely occupied with katenergic processes. They are constantly seizing substances and evolving their stored up energies in the forms of active force.

These two principles suffice to explain the purely chemical phenomena of life. But there are facts which they do not explain, especially the tendency to assume definite forms. The atoms of a molecule cannot be supposed to act preferentially in any one direction. Whence then comes Form?

There are a group of secondary forces called "contact forces," developed by contiguity; they are adhesion, friction, diffusion, electrical tension, attraction, repulsion, and the like. They are the forces of association, and in the inorganic world they determine the phenomena of crystallization. There are many reasons to believe that the ultimate molecule is itself a crystal. The materials furnished by the purely chemical processes become subject to these secondary forces, and thus the origin of Form is explained.

Such is the explanation of this vast question

offered by Dr. J. Bernstein, of Halle, in a recently published monograph.

Can the explanation of the forces of living matter be extended to a resolution of the problems of sensation and consciousness? He thinks not. There is a chasm, a sheer gulf, between the last acquisition of physiological chemistry and the first step of psychology.

How the physical impression excites or becomes the mental sensation, completely eludes our researches. How Consciousness—that fundamental condition of psychical activity—is related to chemico-vital changes, he gives up as an inquiry at present wholly out of our reach.

A contribution to this has been made by an eminent Scotch writer, Dr. John Cleland, in a work published this year, entitled "Evolution, Expression and Sensation." It contains one chapter on the Physical Relations of Consciousness and the Seat of Sensation. The difficulties in the way of the present generally received theory of sensitive conduction and of sensation are forcibly pointed out, and a means of escape from them indicated. It is supposed that when the extremity of a nerve is stimulated the whole nerve and the portion of the brain with which it is in continuity enter into the impressed or active condition, which condition is not conducted from one part to another of the tract, leaving one region as it affects another, but, at all events, for a time, exists simultaneously throughout, and that the consciousness extends from its special state, so far as there is continuity of the impressed condition.

He goes on to say:

"Let it be distinctly understood that I do not say that consciousness resides in the nerve extremities, but only that when the nerves are in the active or impressed condition in their whole extent up to the brain, the consciousness is affected directly by the irritation applied to their extremities. The relation, then, of consciousness to the brain remains totally different from its relation to the nerve. The impressed condition of the cerebral corpuscles produces only excitement of the mind; the impressed condition of a peripheral nerve or its extremity continued up to the brain brings the consciousness into communication with the irritation applied."

The explanation of Form which Bernstein gives would not satisfy the Scotch physiologist. He is not willing to grant that any blind secondary forces can so direct and modify each other as to evolve definite and predetermined shapes. There must be something back of them, some directive intelligence.

In his chapter on the Evolution of Organization, it is contended that evolutions are definite; that "there is morphological design, and when in any line of development the design is completed the evolution ceases, although by the operation of environment or external circumstances variations may continue to occur, and degenerations of diverse kinds may take place. Such views demand for the universe a background or underlying element of spirit."

Probably, were a unity of opinion as to the meaning of this word *spirit* reached, the two writers might be found to agree after all. There is no necessity in assuming that Energy is and must be unintelligent. What is Intelligence itself but Energy?

THE CAUSES OF SUDDEN DEATH IN DISEASE.

The ordinary course of a disease, acute or chronic, is sometimes put a stop to by the immediate, sudden death of the patient, in a manner as unexpected to the physician as it is disagreeable to him. Such cases are pretty sure to be quoted against his skill and foresight, and it is well for him to have ready the explanations which accurate studies of these cases have suggested as likely to explain them.

Some observations on such accidents were published in the Birmingham *Medical Review*, about a year ago, by Dr. W. Hunt. He ascertained that a very common cause was degeneration of the parietes of the heart associated with cardiac dilatation. There is the feeble cardiac impulse, the irregular and intermittent pulse, etc., indicative of the impaired muscular power of the heart, till on some sudden demand, perhaps, on its strength, "it ceases in diastole, and the patient is dead." Our obvious duty in such a case is to guard against any sudden exertion. So, in dilatation of the heart, where the probable compensating hypertrophy is neutralized by further dilatation—the result of a secondary de-

generation in common with the other tissues of the body. A similarly dangerous degeneration of the cardiac walls occurs in certain fevers, especially in diphtheria. LENKER has described two forms—a granular and a fatty. It is also met with in some non febrile diseases, as delirium tremens, acute mania, tetanus, etc.

Again, the heart may fail when it acts, so to speak, at a disadvantage, as in pericardial and pleuritic effusion. Valvular disease, particularly if it leads to aortic regurgitation, may paralyze the heart by over distention, when it will stop in diastole.

Another mode of cardiac death is that from *anæmia*. Here the heart stops in systole, and is found firmly contracted after death. There may be no blood for the heart to propel, as in the rupture of an aneurism, or it may be drawn away from the heart, as occasionally happens in paracentesis of the peritoneum for large effusions, when the removal of the pressure leads to a sudden rush of blood to the part.

In other diseases there is a liability to sudden death from *asphyxia*. Hæmoptysis, spasm of the glottis, etc., may produce death in this way. In embolism and thrombosis of the pulmonary artery, the asphyxia or apnœa is caused by an obstruction to the entrance of blood into the lungs, not, as in the former cases, from obstruction to the entrance of air. Really, sudden death due to affections of the nervous system is rare. It is usually owing to a large amount of hemorrhage in some important part of the brain, as the *pons* or *medulla*.

Interstitial nephritis is a disease liable to be interrupted by sudden death without decided pathological lesions. Some cases were recorded last year in *La France Médicale*, by Drs. DEBOOL and CAPITAN, going to show that the cause was fatal *syncope*.

Both of the sufferers had been in good health up to the time of death, which was not preceded by any morbid phenomena. A third patient had been subject to attacks of suffocation, in one of which he died. There was no trace of valvular lesion in any of these three cases, but the cardiac muscles prevented sclerotic alterations. In discussing the paper, M. LANDOUZY stated that he had made a necropsy a few days before, on a woman who had died suddenly. The brain was normal, but he found considerable hypertrophy of the left ventricle of the heart, and signs of advanced interstitial nephritis. M. DUJARDIN BEAUMETZ drew attention to the fact that medical literature contains a number of cases of very rapid deaths of persons affected with interstitial nephritis, after the hypodermic injection of even very small doses of opium.

Dr. J. PARISE has lately attempted to show that one of the causes of death in cases of moist gangrene is the entrance of putrid gas into the veins, and its rapid passage towards the heart. To support his proposition, he has placed on record two cases of sudden deaths during gangrene of the leg, in which, very shortly after death—an hour and a half and two hours respectively—gas was found in the large venous trunk and in the heart. There is not here any decisive proof that this gas was present before death; but from the great development of gas which is known to take place in the soft tissues in a state of moist gangrene, there is some probability that this is so, and then, if in sufficient quantity, it might in reaching the heart cause sudden death, like air drawn into veins during operations close to the heart. PARISE maintains, that it is thus, and not by any special toxic effect of the gas, whose nature he does not record, that death is produced.

NOTES AND COMMENTS.

Urticaria Produced by the Use of Tinct. Pimpinellæ.

Dr. C. Kaufmann, of Frankfurt am Main. relates a case of which a brief account is given in *Allgemeine Medicinische Central-Zeitung*, February 26th, 1881, in which he ordered twenty drops of tinct. pimpinellæ every three hours, in sweetened water, for the relief of a slight angina. The patient, a girl of sixteen, complained the following day that she had been unable to sleep all through the night, on account of an uncomfortable burning and itching of the skin, and also stated that there was an eruption. Upon examination it was found that the arms, hands, chest, back and ab-

domen were covered with a rash, while the lower extremities were entirely free. There was no general disturbance and the urticaria disappeared by evening, upon the withdrawal of the medicine and dusting the parts with starch powder. Two days later the medicine was again administered, with the same result as before.

The Life of Plants.

In his late work on *The Power of Movement in Plants*, Mr. Darwin observes, it is impossible not to be struck with the resemblance between the sleep movements of plants and many of the actions performed unconsciously by the lower animals. With plants an extraordinarily small stimulus suffices; and even with allied plants one may be highly sensitive to the slightest continued pressure, and another highly sensitive to a slight momentary touch. But the most striking resemblance is the localization of their sensitiveness and the transmission of an influence from the excited part to another, which consequently moves. Yet plants do not, of course, possess nerves or a central nervous system; and we may infer that with animals such structures serve only for the more perfect transmission of impressions, and for the more complete intercommunication of the several parts.

Tattoo Marks as Anatomical Guides.

A Paris letter gives this item:—

Henceforth, be it understood, the dermographic artists will be looked upon as valuable auxiliaries to surgery.

"Why is it," asks Dr. le Comte, who is physician to a regiment of dragoons, "Why is it that such quantities of soldiers die upon the battle field?" And then he replies, confidently: "Simply because of the difficulty which arises in regard to arresting hemorrhages."

The compression of an artery being the best mode of stopping profuse bleeding, Dr. le Comte proposes to teach each soldier first where these vessels are situated, so that he may assist himself while waiting for the surgeon. Therefore, he tattoos an image of some kind upon every portion of the soldier's body where there is an artery.

Injurious Effects of Smoking.

Among other charges brought against the weed should be mentioned one by Dr. Edward Woakes, in an article on goitre, in the *Lancet*. He observes:—

There can, I think, be no doubt about this fact, hat goitre prevails in a mild form among all classes, to a largely increased degree over that which has hitherto obtained. The same may be said of other diseases of a vaso-motor origin, presided over by the sympathetic centres of the cervical region, among which I may mention diphtheria, and laryngeal and nasal affections generally. I am bound to confess it, though I do so with reluctance, as the result of long study of the physiological effects of tobacco, that smoking is largely responsible for this result. Its effects are constantly manifested in the smoker himself, in the form of weakened inhibitory force in the centres primarily influenced by the drug; and, secondarily, the offspring of great smokers exhibit a like impairment of the same centres. Probably, the most inordinate smokers are young men, prior to marriage.

Elongation of Nerves in Tetanus.

At a recent meeting of the Soc. de Biologie, of Paris (Feb. 26th), M. Poncet presented an observation of a case of tetanus, terminating in death, notwithstanding the administration of twelve grams of chloral per diem. No neuritis of the collateral nerves of the injured thumb or of the median nerve of that arm could be found by M. Poncet or M. Mathias Duval, and they were unable to find any trace of the bulbar degeneration noted by M. Amidon in such cases. Elongation of the nerve, successful in a few cases, is generally without avail, and in a case of Clark's, which terminated happily, the tetanic symptoms persisted after the operation. In two cases of Eben Watson's, in a case of Hutchinson's, and another reported by Morris, the elongation was unsuccessful, and this last author considers it dangerous, as augmenting the frequency and violence of the spasms. The recent experiments of Laborde have demonstrated that elongation arrests the sensitive, but not the motor, current in the elongated nerve.

The Synthesis of Quinine.

Hardly any discovery in chemistry would yield grander pecuniary results than an economical formula for the synthesis of morphia or of quinine. About two million dollars' worth of cinchona bark is imported annually, and of the enormous consumption of morphia we have recently spoken. If the exact composition of the cinchona alkaloids was known a great step would be gained. There is a rumor that a process has actually been perfected to manufacture quinine from coal tar, which is theoretically possible enough, but probably not yet an actual fact.

Special Reports.

NO. X.—GONORRHŒA.

Various efforts have been made to discover the supposed specific germs which impart its virulence to the discharge from gonorrhœal surfaces. In 1879, Dr. Albert Neisser, and last year Drs. A. Bokai and A. Finkelstein, reported a number of observations of a peculiar micrococcus found in gonorrhœal pus, whether taken from the urethra or the eye. An abstract of these researches may be found in Schmidt's *Jahrbuch*, January, 1881. Experiments in cultivating these organic forms, and subsequently transplanting them to mucous membranes, seemed to show that they had the power of originating or conveying the disease. Of course, in these, as in all similar experiments, not only are there various liabilities to error of observation present, but even if all these are excluded there remains the uncertainty whether the organic form, the micrococcus itself, is the active agent, or whether it is not, after all, merely the carrier, the means of transportation of a poison in itself strictly chemical and inorganic.

Gonorrhœal Rheumatism.

This obstinate and not infrequent complication should not be mistaken for any other form of rheumatic complaint. There are, perhaps, a few distinguishing points which enable an accurate diagnosis. We may compare two recent portraitures of the disease, to illustrate this. One is by Dr. Cameron, in the *Glasgow Medical Journal*, February, 1881. He writes—

Gonorrhœal rheumatism is most frequent and obstinate in the knees and the smaller joints of the extremities. The accompanying fever is not usually great, while chills are seldom complained of. The pain is often extreme, and effusion takes place rapidly, and sometimes, especially in the knees, in great quantity. In certain cases, the subcutaneous bursæ and the bursal sheaths of tendons are the seats of effusion, as well as the joints. Treatment produces little or no effect; the disease, when severe, is always very chronic, and marked throughout by a disposition to occasional amendments, followed by disappointing relapses. It is not surely assuming too much to say that the articular affection is probably excited by the absorption into the system of some form of septic poison.

The second portraiture is from Prof. Wm. Henry Draper, of New York, given in a lecture reported in the *Detroit Lancet*, Feb., 1881:—

This disease is accompanied with moderate fever. The fever, as a rule, does not run nearly as high as it does in acute inflammatory rheumatism. It has not the same tendency to acuteness of symptoms in any respect. There is great tenderness and great pain on any attempt to move the joints, and the joints may present exactly the same appearance which you find in ordinary acute inflammatory rheumatism, though, as a rule, I think there is not the same tendency in gonorrhœal rheumatism to synovial distention. The disease appears to be confined to the fibrous structures around the joint, and not, in the majority of cases, to present such an intense degree of synovial distention.

The disease, from what I have said of its general characteristics, is a subacute disease; it is a subacute rheumatism, and I do not know how we would distinguish it from an ordinary case of subacute rheumatism which was not associated with gonorrhœa. It has one peculiarity which I would advise you to fix very strongly in your minds, for it will certainly be fixed there when you come to have any experience with the disease, and that is its chronicity. It is the most obstinate, the most rebellious to treatment of all of the forms of rheumatism; the most discouraging. You know that we do not hesitate, now a-days, to make a pretty favorable prognosis of rapid cure in a case of acute articular rheumatism. The success which is met with with the alkaline treatment, and especially with the salicylic acid treatment, leads us to anticipate, in the great majority of cases of ordinary acute rheumatism, a very good result within a week or ten days from the time the treatment is adopted. But I regret to say that neither alkalies nor salicylic acid, nor iodide of potassium, nor colchicum, nor actea, nor any of the remedies that have been used in the treatment of rheumatism seem to have any effect upon this most rebellious form of rheumatism. There is one thing that does cure it, and that is time. If there is any truth in the old adage, that six weeks will cure rheumatism, it is very frequently illustrated in this form of disease, for it will get well as time progresses. And there are a great many remedies, I suppose, that have got the credit of curing the disease, provided they have had the good fortune to be administered during the decline of the disease.

Occasionally abscesses and pyæmia may follow this variety of rheumatism. Dr. Cameron, in the article above quoted, narrates two, one with a fatal termination.

In the first of these, occurring in a gentleman of middle age, recovery only took place after a long continued and most serious illness, accompanied by the formation of several large abscesses in thigh, testicle, and foot. In the second case a fatal result occurred. A young man was admitted a few years ago into my ward with retention of urine, caused by an acute gonorrhœa. The house surgeon relieved him by the use of the catheter. A few days afterwards he complained of "rheumatism" in several joints, and, under the belief that it was a case of gonorrhœal rheumatism, he was received into one of the medical wards, under the care of Professor Charteris. The case developed into one of acute and rapidly fatal pyæmia. On post-mortem examination, numerous abscesses were found in the joints, in the sterno-mastoid muscle of one side, and in the lungs. The urethra was entirely

uninjured by the catheterism, and showed no lesion except the urethritis.

Three cases are reported by Dr. E. Finger, (*Wiener Med. Presse*, 48, 1880), where *purpura rheumatica* was associated with gonorrhœal cases presenting rheumatic symptoms. The connection of the pathological processes was quite clearly made out.

Cardiac Complications of Acute Gonorrhœa.

The complication of gonorrhœal endocarditis is rare. In 1878 (*Deutsche Zeitschrift für Prak. Med.*, No. 50) a collection of seventeen reliable cases, from French sources, was made by Dr. Pfuhl, who added one, fully detailed, to the number. This was a healthy young soldier, 23 years of age, who contracted gonorrhœa May 9, which was followed by gonorrhœal ophthalmia, rheumatism, cystitis, etc., and on June 15th by a continuous sound at the apex of the heart during systole, a feeling of fullness and oppression about the heart, and, on motion, palpitation and local pain.

Dr. Cianciosi records another case of this rare complication in *Bulletino delle Scienze Mediche*, September, 1880. The patient, whose family history was good, contracted a gonorrhœa, which was checked almost immediately by strong astringent injections. The disappearance of the discharge was, however, quickly followed by an undefined feeling of malaise, which became aggravated, and finally accompanied by intense cephalalgia and pyrexia. Auscultation showed at this period a systolic murmur, most distinctly heard at the apex. Respiration 28; temperature 39 Centigrade (102.2 Fahr.). The diagnosis of endocarditis was arrived at, of which no other explanation seemed possible than that it was dependent on the suppression of the gonorrhœal discharge. This shortly afterwards became re-established, and the patient eventually recovered. The author, in explaining the etiology of the attack, exhausts various hypotheses, but eventually adopts that suggested by Klebs in certain cases of rheumatism, viz., an actual emigration of micro-organisms. In this case such organisms found their way into the blood, whence they may have been deposited on the valves of the heart, or in its stroma, with the result of exciting interstitial inflammation, accompanied by the usual train of symptoms.

Pathology of Epididymitis.

Le Progrès Médical, January 29th, contains a report of a communication made to the Société de Chirurgie, by M. Terrillon, on the pathological anatomy of blenorrhagic epididymitis. His conclusions were drawn from a study of eighteen reported cases from experiments on dogs. The important point that these researches develop is that the inflammation is principally in the cellular tissue around the epididymus, rather than in the tissue of that substance itself. A more exact name for the attack would be *peri-epididymitis*. The body of the organ is rarely involved, while the vaginal tunic is always inflamed and often contains liquid, the evacuation of which calms the pain of the disease in a notable manner. Resolution takes place from the periphery toward the centre, but the vas deferens remains for a long time lax and enlarged, and yielding a purulent discharge. M. Terrillon is also of the opinion that the testicular secretion is impaired in quality, and so continues for an indeterminate period.

Gonorrhœal Cystitis.

The *Allg. Wiener Med. Woch.*, No. 45, 1880, gives a discussion at the Vienna Medical Society, in the course of which, referring to the influence of chlorate of potash taken internally, Dr. Mrazek stated that when he was clinical assistant in the department for syphilis he had administered the chlorate in cases of *cystitis* and *cysto pyelitis* arising from gonorrhœa. Altogether there were forty hospital and thirty out-patients who took daily five grams, dissolved in 100 grams of water, with two drachms of cherry-laurel water added to it. Most of these persons took it for twelve to fourteen days, and several for a longer time, so that in most cases as many as sixty grams were taken. Acid reaction commenced in the urine from the second day, and the triple phosphate disappeared from the sediment, which became diminished in quantity and less viscid. The quantity of the urine remained the same, but the urgency for passing it was diminished. When it contained blood at the time the chlorate was given, the quantity of this was increased. No ill consequences resulted from the use of the chlorate, in spite of the fact that most of the patients were in a bad condition of health, and some of them the subjects of tubercle and syphilis. The chlorate must, therefore, be regarded as a valuable aid in treating this form of cystitis and cysto-pyelitis. Of the forty cases treated in hospital, twenty-eight completely recovered, and several others were much improved.

Retention of Urine in Gonorrhœa.

M. Mauriac, in a lecture at the Hôpital du Midi, Paris, recommends that in retention of urine, which is a grave and painful complication, when the stricture occurs gradually and is never complete, a calming and antiphlogistic

treatment is best adapted. For this purpose fifteen or twenty leeches should be applied to the perineum; the patient should also be ordered to remain in a lukewarm bath for one or two hours, and if this does not enable him to micturate, he should be given starch lotion containing a considerable quantity of morphia. Warm and very moist poultices may also be applied over the whole perineum. If these methods are unsuccessful, and if after their employment the retention still continues, recourse should be had, without hesitation, to the catheter.

In the most favorable cases a single evacuation of the bladder by means of the bougie is sufficient to effect a cure. But it is generally necessary to pass this instrument three or four days in succession. In no case should the urine be left until it again distends the bladder and dulls its power of contraction. In fine, then, since the patient cannot void his urine as he could if he were in health, and as he will only imperfectly empty his bladder, he ought to be assisted with the catheter. Baths and soothing applications should also be adopted.

(To be continued.)

Correspondence.

Operations on the Extremities.

Ed. Med. and Surg. Reporter:—

I beg leave to report the following operations, which, I trust, will interest some of your many intelligent readers:—

The first one was on Emma K., aged 11 years. During the month of August, 1878, I was requested to examine her. I found her sitting on a chair, with her right limb very much adducted, the left thigh resting on top of the right. She was unable to walk. The pelvis was elevated on the right side. The body presented a peculiarly bent position, somewhat leaning to the left. The patient was very much emaciated, her appearance betraying that peculiar haggard condition generally resulting from long continued suffering.

I discovered four sinuses in the left heel, one on each side, near the external and internal malleoli, and two further back. After a careful examination I concluded that it was a case of coxalgia of the right hip, and necrosis of the os-calcis, with a probable involvement of the astragalus of the left foot.

On September 10th, 1878, assisted by Drs. Spotts, Detweiler and Bowman, I operated, and, following the method of Erichsen, so highly admired by the eminent Professor of Surgery in Jefferson College, Dr. S. D Gross, I made a horseshoe incision, beginning in front of the calcaneo-cuboid articulation, around the heel, along he sides of the foot, to a corresponding point ont the opposite side. I dissected up the flap thus formed, carefully carrying the knife close to the bone, the entire inferior surface of which was thus exposed. I then made a perpendicular incision of 1¼ inches in length, over the tendo-Achillis, into the horizontal one, and dissected up the two lateral flaps. The os calcis and astragalus both were so much involved that their removal was absolutely necessary, including the external and internal malleoli. The knife, gouge and pliers were the only instruments used.

No arteries having been severed by the operation, the loss of blood occasioned no trouble. The wound was sewed up, a felt splint applied, and drainage was easily effected. The wound was thoroughly cleansed every alternate day, with a solution of permanganate of potash or tincture of calendula, two drachms to one pint of water.

Six weeks after the operation the patient was removed to her home, twelve miles from Reading. The motion of the joint is normal, and the patient able to walk on the foot. After the foot was healed I applied a Day's splint for fracture of the femur, to the right side of the body, from the axilla down, being particularly careful to have it well padded over the hip. To the foot board I attached a strong strip of muslin, which extended across to the foot, where it was carefully fastened. Thus, by lengthening the splint by means of the screw, an extension and counter extension effect was produced, and the limb very much abducted. By these means I finally succeeded in getting the limb in a much straighter line with the body. By applying the weights I succeeded in straightening the limb. Subsequently several sinuses formed below the great trochanter, from which I removed some small spicula of bone, after which the sinuses healed. The patient is enabled to walk from eight to ten squares at a time, by the aid of a cane.

The second patient was Malinda U., aged fifteen and a half years, and weighing fifty-four pounds.

On examination, in February, 1879, I discovered that this patient suffered in the left knee and femur. The leg was completely flexed upon the thigh, standing nearly at a right angle with the thigh. In flexion and extension it would admit of only two inches of motion at the foot. I found two cicatrices, one over the region of the external and the other over the region of the internal condyle of the femur, where formerly there were openings from which a thin watery matter oozed out continually for a long time, which finally ceased, and the openings healed spontaneously. One opening or cloaca remained, however, in the popliteal space, from which a thin, almost transparent pus flowed incessantly. On inserting a probe I readily discovered a sequestra, and after a thorough examination, I felt convinced that it was necrosis of the femur, and that the patella having been drawn backward by its ligamentous attachment with the tibia during flexion of the leg on the thigh, united in that position with the femur, thus preventing extension of the leg.

On April 5th, 1879, assisted by Drs. Spotts. Detweiler, Bowman, and Y S. Ammon, I performed the following operation: I made a semicircular incision, beginning at the outer side of the thigh, about three and a half inches above the

knee joint, and extended it downward and transversely across the tibia, a short distance below the patella to the inner side of the limb. then upward to a point corresponding with the beginning of my incision on the outside of the thigh. Then, dissecting up the flap, I found the patella firmly united to the femur. and extending backward to the front of the head of the tibia. A part of the condyles, including the patella, was sawed off. The articular cartilage of the tibia was removed, and the femur trephined three inches above its extremity where it was sawed off. This, with a longitudinal piece of bone removed, opened access to the inside of the bone, from which a sequestra, $2\frac{5}{8}$ inches in length, and several smaller pieces, were removed. The wound was carefully dressed and placed in an instrument somewhat resembling that of Dr. Price's for excision of the knee-joint. The wound is healed, the femur and tibia have united, and the limb is almost straight, care having been taken not to straighten it entirely.

This patient has since learned a trade, and is now, against my advice, living with her parents, on a farm of 150 acres, where she has been obliged, within the last six months, to hand all the grain raised on that farm in 1880 to the feeder of the threshing machine, to husk corn, milk cows, and perform other hard labor.

Before the operation she had never menstruated, but is regular now. Her general health is very good, and her present weight eighty pounds.

In the after treatment of these cases aconite, veratrum viride, arnica, and a combination of lime, iron and cod-liver oil were prescribed.

Reading, Pa. A. C. Detweiler, M.D.

Treatment of Pneumonia.

Ed. Med. and Surg. Reporter:—

A recent article, "Treatment of Pneumonia," W. C Wile, M.D., (Medical and Surgical Reporter, March 26th, current volume, pages 360 and 361) has induced me to write and to offer an expostulation against not only an indiscriminate use of the lancet in the treatment of said disease, but also against this thing of blindly following the teachings of a friend or favorite, even against the teachings of the leading minds of our day. Now, Dr. Wile, because Dr. Corson gave such valuable advice concerning ice in the treatment of the eruptive diseases, measles and scarlatina, and also advocates bleeding in pneumonia, does not stop to consider whether bleeding is indicated or not, but plunges the lancet into the arms, or elsewhere, of all persons afflicted with a certain lung trouble that he (Dr. Wile) pronounces to be pneumonia. He cites five cases, three of which were under thirty years of age, one seventy-three, and the other eighty-two years of age. His cases of pneumonia, before Dr. Corson's articles were published, were very fatal, indeed, so much so, that he had a dread of treating it. Now he had Corson's articles to draw from, and of the five cases mentioned, two were in their shops at work in one week, while with the other three the disease "ran a mild course and made a rapid recovery." Do these writers put themselves on record as advocating such a procedure without thinking of what the result may be among a certain class of beginners who must have others think, to a greater or less extent, for them? Are the finger posts our fathers erected for our guidance lost, or do we not yet possess a sufficient number to conduct us safely through? Must we neglect entirely the exhausted condition of a certain class of our patients, and bleed them anyhow? God forbid, for if we do I certainly feel that we will cut short the disease, but we will also cut short life with it. When bleeding is indicated, what practitioner will refuse to resort to the lancet? When it is unsafe, would it not be better to never touch one, than to endanger life by using it too freely? Because opium will relieve pain, must we give it to every patient suffering from pain, whether there is an idiosyncrasy or not? Because quinine is our sheet anchor in malaria, must we resort to it in twenty grain doses in every case of malarial fever we may encounter? Dr. Corson claims too much, and by sowing the seeds he is sowing, endangers lives he does not dream of. Because he, an old hand at the helm, can guide the boat safely over the treacherous breakers of disease by resorting to a practice great minds pronounce dangerous, is it a reason for him to teach inexperienced young doctors, all over these broad States, to bleed old and young, weak and strong, indiscriminately, whenever said doctor may imagine a patient has pneumonitis?

With all due deference to the age and experience of Doctor Corson, and with a kindly feeling to Doctor Wile, I must, nevertheless, enter my weak protest against the revival of a practice at once dangerous and hurtful in all its tendencies.

I could quote authors of the age of blood letting, who invariably advised care in certain cases, but I will not lengthen what I have written by doing so. J. E. Stinson, M.D.

Montague, Texas.

Salicylate of Sodium in Rheumatism.

Ed. Med. and Surg. Reporter:—

I was called, March 26th, to see a little girl of Mr. C.'s. Found her suffering from an attack of acute rheumatism; the suffering was very severe, the weight of the bed clothes causing severe pain. I put her on large doses of potass. bicarb., with Dover's powder, to ease pain. The next morning I found her no better; changed treatment to—

℞. Salicylate of sodium, ℥ ss
Glycerine,
Water, āā ℥ ij. M.

Dose, one teaspoonful every two hours until three doses are taken, then only one-half the amount.

I called the next morning and found her entirely easy and sitting up in bed; the mother claimed that all pain was gone after the second dose. Within three days after the time this treatment was commenced, she was around the house, and still remains well. J. D. Appley, M.D.

Susquehanna Depot, Pa.

In this connection we may mention salicylate of cinchonidia as proving equally valuable in rheumatism and neuralgia.—Ed.

News and Miscellany.

Opening Exercises of the Medico-Chirurgical College.

The opening exercises of the Medico-Chirurgical College took place at noon, April 4th, 1881, at the rooms of the College, S. W. Corner Broad and Market streets.

At the appointed hour the exercises were commenced with prayer by Rev. C. F. Turner, after which the President of the College, Prof. George P. Oliver, M.D., delivered the opening address, explaining the aims and purposes of the College. This was followed by addresses from Rev. P. S. Henson and Rev. C. F. Turner, both of whom expressed much interest in the future welfare and success of the College.

We make the following extracts from the President's address, as indicative of the spirit and plan of the new association:—

Ladies and Gentlemen:— * * * *

To establish a medical college in Philadelphia that will be an honor to our profession, and will be able to compete with that grand old monument of human genius, my own time honored alma-mater, the University of Pennsylvania, or that shall successfully vie with her prosperous rival, the Jefferson College of Philadelphia, is a work of no ordinary character, and should be enough honor for any Faculty to achieve during an entire lifetime. We wish the City of Brotherly Love to continue to be the great centre and metropolis of medical teaching in the United States, and while we wish success to still attend the two great colleges already flourishing here, and hope that even greater triumphs will be accomplished by them, yet to day we present another college for public favor, which we trust will not be devoid of attracting powers, but will prove to be a blessing to all who may ever enter within her walls. * * * *

How much longer shall we hear of eminent Professors allowing themselves to become even *passive* agents in lowering the standard of medical education, by admitting students to their colleges who have never read an hour with a medical preceptor, and who are not gifted by nature, or fitted by education, to grasp and hold on to the necessary amount of knowledge that is requisite to make them successful practitioners of medicine. It is a sad misfortune, that hundreds of young men who attend a few lectures receive a diploma, and thereby get a license to play the role of a physician, and make an attempt to perform the responsible duties of a Doctor of Medicine, even before they have acquired a knowledge of such elementary requirements of the profession as would be necessary to secure their admission into the junior class of any respectable college of medicine. The consequence is that only about twenty out of every hundred who procure diplomas continue in the practice of medicine, and a far less number ever attain to any great eminence in the profession. Knowing these facts, it seems strange that respectable and well-meaning physicians, who are not connected with colleges, do not see to it, and discourage young men, when they know they have neither education nor aptitude to overcome the difficulties attending the acquisition of that comprehensive instruction so essential to insure success in the varied and onerous duties devolving on a physician. It is the intention of the Faculty to use every means that can be made available to advance students and to render them proficient in the duties of their profession. We deprecate the system of cramming now in use in many medical colleges in various parts of the country; crowding into two winter sessions the entire medical tuition of the student. Owing to the shortness of time, sufficient instruction cannot be given, and the student fails to complete his medical education properly. With a view of elevating the standard of medical education, our college has adopted a curriculum embracing a full three years' graded course. By this action we believe we will assist in placing some safeguards around society that are being sadly neglected by many medical colleges in America. No pupil will receive the honor of the Doctorate from the Medico-Chirurgical College unless he has been faithful in his attendance to the lectures, and has fully qualified himself for the degree by having acquired a knowledge of the essentials of the seven fundamental branches of medicine. * * * *

The mystifying influences which have surrounded the domain of medicine, and retarded its progress for centuries, are swiftly passing away, and now, under the use of the *anæsthetic*, the *knife* and the *microscope*, our profession is no longer to be regarded as a mere *art*, but by the accumulation of its thousands of truths, it is rapidly crystallizing into a *science*. Still, medicine has not yet developed all the embryonic treasures that lie hidden in the womb of time which need but the ready hand of persevering industry to bring them into life and usefulness. Shall we who live in this enlightened age forget our mission in life, and in the hurry and bustle of an aimless career, allow these golden opportunities to be taken hold of by men who are gifted with no greater mental powers, nor blessed with any more favorable circumstances than we are? Shall we stand idly by and see these men using the most diligent research, and exhibiting the most enduring energy, and thereby achieving lasting victories, which, with the same amount of exertion on our part, would have placed our names on the same roll of honor, and would have given us the same meed of praise, as is now so justly bestowed upon them?

To both old and young in our profession, who are resting satisfied with the laurels already gained in former days, we desire to say, fall in line and march to the front, assist your brethren to break down the formidable barricades that have been erected by unscrupulous men, who have almost run their course, but who are still attempting to control the destiny of our profession. To our friends who have honored us with their presence to-day, we tender the thanks of grateful hearts. We feel that our success will not depend upon ourselves alone; much will be due to the encouragement we may receive from those who are in full sympathy with us. Give our College and our sister colleges who are engaged in this noble work your aid and counsel, and the great object will, in a short time, be effected. We know we will have a severe strug-

gle, at first, but we are determined to hold on, even though we have to fight the battle alone. Other colleges may falter, as one in New York already has, but with the full assurance that we are doing right, we intend, with the assistance of Divine Providence, to persevere manfully, until victory shall crown our efforts.

"Let us then be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labor and to wait."

The Pennsylvania State Medical Act.

We have been requested to publish the full text of the Act recently brought before the Legislature for the regulation of practice in this State. Although our columns are considerably crowded with other matters, we believe the text of the Act will be read with interest, both by many in and out of the State.

AN ACT to regulate the practice of medicine, to establish a State Board of Health, and to make an appropriation therefor.

SECTION 1. *Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same,* That the Governor, by and with the advice and consent of the Senate, shall appoint six persons, who, with the Secretary, shall constitute the State Board of Health. The persons so appointed shall hold office for six years, provided that the terms of office of the six first appointed shall be so arranged that the terms of two members shall expire in two years, the terms of two shall expire in four years, and the terms of two shall expire in six years. And the vacancies so created, as well as all other vacancies occurring otherwise, shall be filled by the Governor, by and with the advice and consent of the Senate; and provided, also, that appointments made when the Senate is not in session may be confirmed at its next ensuing session.

SEC. 2. The State Board of Health shall have the general supervision of the interests of health and life of the citizens of the Commonwealth; it shall have authority to make such sanitary investigations as it may, from time to time, deem necessary in improving the public health; it shall pass upon the competency of practitioners of medicine; it shall have the general supervision of the collection of the vital statistics of the Commonwealth; it shall, at the session of the General Assembly next following its creation, report for legislative action a code of sanitary laws; it shall prepare an annual report of its operations, which shall be submitted to the Governor; it shall diffuse a knowledge of the means of obtaining individual and public health, and of preventing disease.

SEC. 3. The first meeting of the Board shall be held within fifteen days after its appointment, and thereafter in January and June of each year, and at such other times as the Board shall deem expedient. The meeting in January in each year shall be in Harrisburg. A majority shall constitute a quorum. The Board shall elect a Secretary, who, by virtue of such election, shall be a member of the Board and its executive officer. The members shall choose one of their number to be President, and they may adopt rules and by-laws for their government, subject to the provisions of this Act.

SEC. 4. No member of the Board, the Secretary excepted, shall receive compensation, but all proper and necessary expenses of members, while engaged in the service of the Board, shall be paid by the State upon the presentation of an itemized account, with vouchers annexed. The Secretary shall receive an annual salary of three thousand dollars, which shall be paid in the same manner as salaries of other State officers are paid. Said Board may, from time to time, engage suitable persons to render sanitary service, and to make or supervise practical or scientific investigations, and examinations requiring expert skill, and to prepare plans and reports relative thereto; but such special sanitary service shall not cost more than three thousand dollars in any one year. The total expenditures of the Board shall not exceed the sum of eight thousand dollars in any one year.

SEC. 5. The sum of sixteen thousand dollars is hereby appropriated from the State Treasury for the purposes of this Act. The expenditures properly incurred by the authority of said Board, and verified by affidavit, shall be paid by the Treasurer, upon the warrant of the Auditor General.

SEC. 6. The standard qualifications of a practitioner of medicine, surgery, or obstetrics in this Commonwealth shall be and consist of the following, namely:—

A good moral character.

A thorough elementary education.

Three years' study of medicine in its various branches, under a competent preceptor.

Attendance upon two full courses of lectures in a legally chartered medical school.

A satisfactory examination, before or on graduation, in human anatomy, human physiology, pathology, chemistry, materia medica, obstetrics, practice of medicine, surgery and public hygiene.

A diploma received in regular manner from a chartered medical school duly authorized by law to confer upon its alumni the degree of Doctor of Medicine, and

A license granted as hereinafter set forth.

Every applicant for such license shall furnish to the State Board of Health satisfactory proof that he is possessed of the qualifications enumerated in this section. He shall deposit a copy of his diploma in the office of the Court of Common Pleas of the County in which he may sojourn or reside, said copy to be a matter of record and open to public inspection: *Provided*, that any resident practitioner of medicine, surgery, or obstetrics, who had been in continuous practice in this Commonwealth for a period of not less than five years prior to the passage of the Act of Assembly entitled "An Act to protect the people of the Commonwealth against incompetent practitioners of medicine, surgery, or obstetrics," approved the twenty-fourth day of March, A. D. 1877, shall file in the office of the Court of Common Pleas of the County where such person intends practicing, his affidavit setting forth the time of continuous practice, and the place or

places where such practice was pursued in this Commonwealth. Said affidavit shall, if found by the State Board of Health to be correct and true, be deemed sufficient evidence of qualification to practice medicine, surgery, or obstetrics, and said Board shall issue the license hereinafter provided for.

SEC. 7.—The State Board of Health shall examine every diploma or affidavit of competency recorded and filed in the offices of the said Courts of the various counties; and said Board shall be the judge of the genuineness of said diploma, and of the truth of said affidavit of competency. If said diploma or affidavit of competency be found genuine and true, and if the person therein named be the person applying for a license to practice medicine, the State Board of Health shall issue such license, which shall be conclusive evidence of the right of the lawful holder of the same to practice medicine in this Commonwealth. In addition to the persons already mentioned as entitled to such license, any person who shall submit himself to such examination as the said Board may require, and who shall pass an examination satisfactory to the Examiners, under such restrictions and regulations as the Board may prescribe, shall receive a license from said Board of Health to practice medicine, surgery, or obstetrics, and shall be entitled to all the rights and privileges herein mentioned. The officers of said Board shall have authority to administer oaths and to take testimony in all matters relating to their duties. Said Board shall furnish to the Prothonotaries of the several counties a list of all persons receiving its license. Said Board shall have power to refuse or revoke its license for just and proper cause.

SEC. 8. It shall be unlawful, on and after the first day of January, A. D. 1882, for any person not qualified and licensed by the State Board of Health, according to the sixth and seventh sections of this Act, to practice medicine, surgery, or obstetrics, or to collect any fees for medical, surgical, or obstetrical services.

SEC. 9. Candidates for examination by the State Board of Health shall pay a fee of five dollars, which shall be returned to them if licenses be refused. Examinations may be made, in whole or in part, in writing, and shall be of an elementary and practical character, but sufficiently strict to test the qualifications of the candidate as a practitioner.

SEC. 10.—Any person shall be regarded as practicing medicine within the meaning of this Act who shall profess publicly to be a physician, or to prescribe for the sick, or who shall append to his name the letters "M. D.;" but nothing in this Act shall be construed to prohibit gratuitous services in cases of sudden emergency. And this Act shall not apply to commissioned surgeons of the United States army and navy.

SEC. 11.—Any itinerant who shall sell any drug, nostrum, ointment, or agency of any kind, intended for the treatment of disease or ailment, or who shall, by writing or printing, or by any other method, publicly profess to cure or treat disease, injury, or bodily ailment whatsoever, shall pay a license of one hundred dollars a month, to be collected in the way now prescribed by law for peddlers.

SEC. 12. It shall be the duty of practitioners of midwifery in this Commonwealth to register their names and post-office address in the office of the Court of Common Pleas of the county where they reside; and said practitioners of midwifery shall be required, under penalty of ten dollars, to be recovered in any Court of competent jurisdiction in the Commonwealth, to report to the Prothonotary of said county, within thirty days of their occurrence, all births and deaths which may come under their supervision, with a certificate of the cause of death and such correlative facts as the Board may require.

SEC. 13. It shall be the duty of all health officers and Boards of Health in the State, all officers of the State, the physicians of all incorporated companies, or the president or agent of any company or institution chartered, organized, or transacting business under the laws of this Commonwealth, so far as is practicable, to forward to the State Board of Health any information bearing upon public health which may be requested by said Board.

SEC. 14. Any person who shall offer for record a copy of any diploma to practice medicine which shall have been issued to any other person, or shall offer for record a diploma or affidavit of competency issued or obtained fraudulently, or in violation of the laws of this Commonwealth, or in violation of the charter of the institution conferring said diploma, shall be deemed guilty of a misdemeanor, and upon conviction thereof, shall be punished by a fine of not less than three hundred dollars nor more than five hundred dollars, or imprisonment, at hard labor, for not less than one nor more than three years, or both, at the discretion of the Court, and his license shall thereby be revoked. And any person who shall in any other respect violate or fail to comply with the provisions of this Act shall be deemed guilty of a misdemeanor, and on conviction, before any court of competent jurisdiction, shall be sentenced to pay a fine of not less than two hundred dollars nor more than four hundred dollars for each and every offence, for the use of the county wherein such misdemeanor is committed, and his license shall thereby be revoked.

SEC. 15. All Acts or parts of Acts inconsistent herewith, be, and the same are, hereby repealed.

On Vaccination.

In consequence of the aggressive conduct of the Belgian Anti-Vaccination League, the Belgian Academy of Medicine appointed, last December, a committee of three members, for the purpose of undertaking an exhaustive examination of the whole subject, and of the arguments of the objectors. At the end of January, M. Warlomont, Director of the State Vaccination Institute, read an elaborate report, in which he submitted to the Academy the following propositions: 1. Without vaccination, hygienic measures and means, whether public or private, are powerless in preserving mankind from the smallpox. 2. The belief in the danger of vaccinating

and revaccinating during the presence of a variolous epidemic is not justified. We can no more cultivate variola by sowing vaccinia, than we can barley by sowing wheat. 3. Vaccination is always an inoffensive operation when practiced with proper care on healthy subjects. It gives rise to fewer and less serious accidents than simple piercing of the ears. 4. It is highly desirable, in the interest of the health and lives of our countrymen, that vaccination and revaccination should be rendered compulsory.

An Astounding Argument.

An extraordinary argument was used by Mr. Henry Bergh, President of the Society for the Prevention of Cruelty to Animals, in the course of an address against vivisection, which he delivered in Albany, in February. It was as follows:—

"As another proof of the profane extremes to which these dissectors of living animals will go, Robert McDonald, M.D., on being questioned, declared that he had opened the veins of a *dying person*, remember, and had injected the blood of an animal into them many times, and had met with brilliant success. In other words, this potentate had discovered the means of thwarting the decrees of Providence, where a person was dying, and snatching away from its Maker a soul which He had called away from earth!"

If anything can surpass this in absurdity, it would be pleasant to have it produced.

Influenza in Charleston, S. C.

Under date of March 21st, Dr. F. P. Porcher reports to the National Board of Health a form of *influenza* prevailing in and near Charleston. The symptoms are some fever, catarrh, almost constant cough, some pains in the limbs, but not so marked as in the dengue fever of last summer; there is usually headache, with redness of the tongue, and not unfrequently vomiting. The fever is sometimes high, but the prostration following is not very decided. The eruption of dengue is wanting, but in two cases swelling and suffusion of the face have been observed. The disease has extended to Columbia and elsewhere, and has affected a large number of persons, white and colored, throughout the lower portion of the State.

Daily Report of the American Medical Association

"A *daily edition* of the *Southern Clinic* will be issued during the meeting of the American Medical Association, in Richmond, Va.

This will be for gratuitous distribution, in honor of the occasion." C. A. Bryce.

The New German Pharmacopœia.

It has been decided by a respectable majority of the Committee on the Revision of the new Pharmacopœia for the German empire that the Latin language should be retained in its preparation. The reasons given are that it will thus be more useful to those not reading German, that there is greater accuracy in the Latin than the German names, and that custom having sanctioned the Latin there is no good reason for abolishing it.

Items.

—At the meeting of the Academy of Sciences in Paris, on March 12th, the Boudet prize of 6000 francs (£240) was awarded to Professor Lister, for his application of M. Pasteur's researches to the improvement of the art of healing.

—A severe outbreak of trichinosis in a village near Beirut, Syria, during which several of the sufferers died, was traced to the flesh of a wild boar which had been eaten in an underdone condition by the villagers. A full account is given in the *Lancet*, March 19th.

—The American Laryngological Society will meet in Philadelphia during the second week in May. A full gathering of the members is expected, and the brethren of Philadelphia are preparing for them a cordial reception. Dr. J. Solis Cohen, of our city, is the President for 1881.

—A Paris medical exchange says: "In Havre, American pork is to be inspected, and if found free from trichinæ its sale will be allowed. As an offset to this wise regulation, the Cyprian sisterhood is to be relieved from police control, so that henceforward pig meat will need a government stamp to make it current, but frail flesh will be at liberty to spread syphilis. Is this change a gain?"

—The next annual meeting of the Medical Society of New Jersey will be held in the drawing-room of the Ocean Hotel, at Long Branch, on the fourth Tuesday of May, 1881, at half-past seven P.M. The hotel will be in readiness for the accommodation of about three hundred guests. Orders for commutation tickets over the Central Railroad may be procured from the Secretary. Wm. Pierson, Jr.,

Orange, April 26th, 1881. *Secretary.*

MARRIAGES.

ALLISON—LINK.—In Burlington, Kansas, March 30th, by Rev. J. H. Ralston, Dr. John M. Allison, formerly of Philadelphia, and Clara Link, both of Burlington.

BRUGLER—ANDERSON.—At Rose Lawn, Forest Grove, Bucks County, Pa., March 23d, by Rev. Jacob B. Krewson, De Witt Brugler, M.D., of Carversville, and Hannah, daughter of Lewis Anderson, of Centreville.

MARKELL—JUDD.—In New York, Wednesday, April 13th, by Rev. C. S. Robinson, D.D., Jacob Markell and Emma B., only daughter of Walter L. Judd, Esq.

DEATHS.

AVERY.—At No. 165 East 49th street, New York, April 14th, Amos R. Avery, M.D., of Forestville, N. Y., aged 75 years.

COLLINS.—At the Grand Central Hotel, New York City, April 10th, 1881, Clarkson G. Collins, M.D., of Great Barrington, Mass., in the 61st year of his age.

HERZOG.—In New York, Tuesday night April 12th, after a brief illness, Dr. Max Herzog, in his 51st year.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1215-1267eow ROBERT SHOEMAKER & CO.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C 20	H 24	N 2	O 2
Quinidia do	15 "				
Cinchonidia do	15 "	C 20	H 24	N 2	O
Cinchonia do	15 "				
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

Lecture.

ON TENIA AND TENIAFUGES.

BY DR. CARL BETTELHEIM,

Of Vienna.

Translated from the *Klinische Vorträge*, for the Medical and Surgical Reporter.

Gentlemen: The determination of the species—whether Tenia solium or Tenia mediocanellata, is unnecessary, and I have found that the expulsion of one variety is no more difficult than that of the other.

Having satisfied yourself of the existence of a tapeworm in your patient, the next point is to consider any symptoms which may contraindicate the treatment for its expulsion.

Contraindications are: any anatomical lesion of the stomach (gastric ulcer, acute catarrh, etc.): all febrile affections, wet-nursing, convalescence from severe illness, the menstrual period in females, pregnancy, weakness from old age, and in sickly children, if the presence of the worm does not produce serious inconvenience. Anæmia, if not too extreme, is not a positive contraindication.

If there are no symptoms which would lead you to delay an attempt at expulsion, you should then appoint a time for the same, when you may be at leisure to give it your entire attention, because if you are unable to do so you may be disappointed in the results; something may occur which will cause a failure; you must remember that your remedies only sicken the worm for a time, and that if it recovers before expulsion is effected, it may attach itself to the walls of the intestines, and thus frustrate all the efforts which you have made. Carefully examine all fecal discharges. I have known attendants to declare that they contained no worm, when upon an examination I have found them to contain the entire worm with the head all rolled into a small mass.

My cure lasts from forty minutes to somewhat over four hours. I order the patient to abstain from all food (water excepted) for from eighteen to twenty-four hours before beginning the anthelmintic medication, and at the same time give suitable purgatives, the best of which are, in my estimation, castor oil or powd. jalap; a tablespoonful of the oil or from 0.3 to 0.5 (4½ to 8 grains) of the powder, morning, noon and night, and another dose three or four hours before giving the anthelmintic. The latter I prescribe as follows:—

Cort. rad. punic granat., 2—400 = (℥ vj-xij). Macerate for twenty-four hours in aquæ destill., 5—600 = (f. ℥ xvj-xix), and then evaporate until the strained residue measures 200—300 = (f. ℥ vj-ix). Care should be taken that the bark used is fresh, as it deteriorates by age.

The resulting decoction, which should be of a clear, dark brown color, is administered by means of an œsophageal tube, which is introduced to about the middle of the œsophagus and the fluid poured into the same by means of a small glass funnel.

The patient is then directed to remain as quiet as possible, and if the remedy is not vomited within half an hour or an hour, the worm is generally expelled in from three-quarters to four and a quarter hours.

If the bowels do not move in an hour and a half after the administration of the medicine, an-

other dose of the purgative or an enema should be given; this should, however, not be done sooner, as it may cause vomiting.

Grown persons generally allow the œsophageal tube to be introduced without much remonstrance, but some, of course, have an uncontrollable dread of such a procedure, and will rather drink the entire dose than submit to it.

If the decoction is vomited within a short time after its introduction into the stomach, 3 or 4 grams (45 to 60 grs.) of ethereal extract of male fern, in pill form, or 60 to 75 grs. of knissin, in powder, should be given in 0.5 gram (7½ grs.) doses every half hour to hour. The success of these remedies is, however, not as rapid nor as sure as my method.

Should the worm be only partially expelled and hang from the anus, the administration of anthelmintics must be continued. The patient should sit upon two chairs, and the worm carefully rolled on to a stick; as soon as the worm resists this procedure, having fastened itself to the intestinal walls by means of its suckers and hooks, the patient should be directed to lie upon his left side, and an enema of lukewarm water, to which a few drops of turpentine have been added, should be given, forcing the same as far up the intestinal canal as possible.

If the worm should not be expelled because the medicine is vomited as soon as taken, the same procedure should be repeated in a few days, only then the anthelmintic must be introduced into the stomach in three or four portions, at intervals of fifteen or thirty minutes.

For children I use a smaller quantity of the decoction, 100 to 150 grams (3 to 5 fluid ounces), and if vomiting is produced too early, I continue it in doses of 20 to 30 grams (5 to 8 drachms), every forty to ninety minutes.

As soon as the worm is expelled, the patient should be allowed to partake of some good nourishing soup.

CLINICAL STUDIES OF INEBRIETY.

BY T. D. CROTHERS, M.D.,

Superintendent of Walnut Hill Home, Hartford, Connecticut.

I have intimated clearly, from the study of many cases of inebriety, that no degree of faith, or prayer, or earnest, honest intention on the part of the patient, can save him from inebriety. In all cases, I am convinced, as a physician, that these agencies are of great value, and always urge my patients to a higher living based on faith, the exercise of prayer and a determined will to rise above the entailment of disease from which they suffer. I also urge that these forces cannot be made available unless supplemented by active work, the use of physical agencies, the exact application of means and methods which shall reach out and control the organism. Some physicians have taken exceptions to my views of the secondary value of spiritual forces in the treatment of these disorders, and have written to me detailing cases which have recovered by this means; also cases which have failed from the want of them. I think that any of these physicians will find, from a study of many different diseases, cases which have recovered in a manner more or less mysterious, which might be fairly attributable to the same spiritual forces, such as faith and prayer. Yet, the application of these means to other cases of the same disease would always fail, especially if they are used exclusively. The value of faith and prayer in inebriety is, in all probability, nothing more than the effect of mind on the body, and the application of the principle of hope and confidence which every physician seeks to inspire in the patient's mind, no matter what the disease may be. If this is trusted, to the exclusion of other means, failure will follow; and yet not unfrequently cases of disease go on to recovery, buoyed up on this, or *harmless infinitesimals*, which simply give a tonic activity to the mind and permit the full action of nature. In many cases I have been convinced that the shock to the mind from the presence of some powerful mental emotion was sufficient to arrest diseased action, and even change the malady and its progress. Illustrative cases of this character are seen in those persons who exhibit a total change of character and habits, either from religious emotion or from grief or fear. Or those who suffer from disease, complicated with a strong nervous element. I have seen inebriates who became suddenly converted make a radical change of all their habits, and after a time become melancholic, demented and die. Here was a change of the nature and character of the disease, from the presence of mental emotion. In another case of supposed mania and melancholia, the advent of a change of fortune restored him to a clear, vigorous activity.

I do not propose to discuss this question of the power of prayer or faith in inebriety, but wish simply to present some studies of cases which bear on this point, and which I think furnish the most rational conclusions. The first proposition I make is this: that no exercise

of faith and prayer or honest intention exclusively, can either save the inebriate or prevent him from falling. In a study of ten cases on this point, I found that seven had been, before and after the beginning of inebriety, active church members, had experienced conversion and led active lives of faith and prayer for longer or shorter intervals, depending on circumstances. Two of these were periodical inebriates, and had, during the free interval between the attacks. led a most consistent Christian life of faith and prayer. One of the seven exhibited the strange delusion of religious mania when drinking; at all other times he was a quiet skeptic and doubter. but when once under the influence of alcohol he was the most ardent religious devotee, exhorting with great enthusiasm, and asking the prayers of every person he met, to save him. His mind seemed filled with intense fear of failing to get to heaven, and every thought and exertion seemed directed to this end; but secretly he drank constantly, never to be stupid, but just enough to keep up a degree of excitement. This would last for two or three weeks, then merge into a low form of nervous fever, from which he would recover and remain sober for an indefinite time. This was a form of emotional inebriety which is sometimes seen in those who are either quarrelsome or excessively happy, benevolent or parsimonious, while using alcohol. The other three had been good church members before inebriety came on, but on becoming inebriates left the church. I am confident that all chronic inebriates have a diseased emotional nature which finds a natural outlet in religious activity, and that the exercise of faith and prayer is a contagious element which they feel readily, from their nature and the surroundings. This can be seen in all communities where every temperance and revival movement carries these men to the front rank and among the earliest converts. Also in every political excitement and social change, the most enthusiastic and excitable partisans are inebriates.

The following case is significant, in both its cause and the means which failed in the treat ment. H. A., a clergyman, an active, hard working man, whose history gave no evidence of any inherited taint; from childhood he was an abstainer and rigid temperance man. After conducting a series of revival meetings extending over many months, becoming worn and exhausted, one day, during the administration of the communion, the idea impressed him that this wine would be of medicinal value. It was the custom to store what remained of the wine at the parsonage, and when the service was over he drank some, in his study; the effect was so pleasing that he continued to drink, and before night became literally intoxicated. The next communion season he was seized with an intolerable desire to drink wine again, which he gave way to after the service, in his study, and became intoxicated as before. This alarmed him, and he sought, by his power of will and prayers, to prevent its recurrence. The next period was marked by the same fall and intoxication. After this intoxication the desire left him and only returned when pouring out the wine at the next communion season. Two years later I was consulted. He was nervous and much debilitated; was using patent bitters every day; had not been to the communion table for many months; was filled with fear that he would drink, and afraid of falling with the least temptation; hence was praying incessantly, and using every means to prevent such a recurrence by the exercise of strong will and faith. He said he was impelled to go and buy wine, and only after did he realize the danger. He could not tell why, except that the evil spirit impelled him to do so. He had exchanged pulpits and invited a brother clergyman to be with him at the communion season, and direct contact with wine was avoided, but a strange, nervous agitation followed, which soon became positively painful and increased until all sense of pride or consciousness of his condition was lost; then he resorted to the most cunning intrigue to procure wine; never seemingly able to realize his condition until after an attack of intoxication. If he was watched at this season he could keep from using wine; this would last a week or more, then all restraint was lost. During these attacks he at times exhibited a remarkable sensitiveness to conceal his condition. He preached more earnestly and was very religious and exciteable, also more enthusiastic, where he had been cool before. I advised that he give up all work, and prayers, and go out into the country, put himself in some kind friend's control, work in the open air and keep perfectly cool and free from excitement; that he was suffering from dipsomania, which would break out more prominently, or develop into some other form of disease. His clerical advisers insisted that he could help himself by being more in earnest and depending more on divine help. Acting on this advice he obtained a short leave of absence to visit Europe, and returned a few months later, having drank more there than at home. From this time his course was rapidly downward, and

to-day he is an inmate of an insane asylum. This man was most conscientious, and anxious to do right, and honestly tried to check this desire for drink by both his will and the exercise of faith and prayer. He was suffering from dipsomania, brought on by overwork and cerebral exhaustion, and could only be benefited by the application of exact remedies following the line of known physical laws. Had he been placed in some hospital for inebriates, recovery would have followed.

The second case was that of a farmer who came home from the army, where he won distinction for bravery, but had acquired periodical inebriety. I was consulted by letter, and urged the physical nature of his malady and the necessity of physical treatment. This he objected to, stoutly asserting his ability to stop any time. Being a favorite in that community he became the object of interest for both the temperance and church reformers, who sought, by the application of all their means, to save him. During the next three years he joined the church, relapsed, was received back again, was very prominent and earnest, then became cold and slanderous; also united with the temperance society, worked well for a time, and relapsed. Was the subject of the united prayers of the community for many years, and signed the pledge repeatedly; made innumerable efforts and resolves to stop, but failed; was a praying man, and sought every means to get help from this source; then gave up in despair. He wasted his property, and, in a paroxysm of drink, set fire to his building and perished in the flames. Here the failure was simply in not applying remedies that were adequate to meet his case. He was suffering from a physical disease which could be reached by physical remedies.

These two cases may stand as typical of many others who are disappointing their friends, and are enigmas to all who come in contact with them. Always attempting to recover, and with extreme confidence entering upon every effort that promises this end; then relapsing very unexpectedly, and only to repeat this process at an uncertain time and moment.

Another class of cases have come under my care that are equally enigmatic, but more common. Like the others they have disordered emotional symptoms, are either elated or depressed; at times seem to have great power of control, passing through many temptations with great firmness; then, all unexpectedly, relapse on the slightest provocation.

The following is a typical case of this character: Brown, a lumber merchant, an intensely active man, with healthy parentage, who had been an occasional drinker from 20 years of age, began to use alcohol to excess when 34 years of age. Five years later he was an irregular inebriate, drinking very severely for a week or more, then reforming for an uncertain interval, varying from a few days to a year. He was a leading man in the community, and the object of great solicitude by his friends. From his brother-in-law, a physician, I obtained the following history: He drank always at home, in his room, and would not go out, but insisted on doing business and having friends come there to him. He was either very jubilant and hilarious or stupid and drowsy. All advice and pleadings of friends were listened to with unusual politeness. Clergymen and others would come and pray for him at these periods, to his apparent pleasure. He would become violent if any attempt was made to take away the spirits, claiming he would stop when he pleased. Then, suddenly, he would call for a pledge, sign it, and stop at once, go to church, exhibit great zeal for the temperance and church work, or go to saloons and talk, and attempt to help inebriates reform by advice and money. These efforts would last an uncertain time; then, unexpectedly, he would begin to drink at home again. Sometimes he would "swear off," as he termed it, for a year or more, and remain rigidly temperate up to the last moment, then drink in a manner equally mysterious. When he pledged to abstain for a certain time, it was carried out rigidly, to the exact moment. If during his paroxysm of drink he could be induced to sign a pledge, it was the end of all further intoxication or drinking. This puzzled his friends, and seemed purely a vice which he could check at will. At times he made active exertions to build himself up by the exercise of faith and prayer, and never seemed to realize his condition or be conscious of the excess. He continued in this way for many years, and finally died of acute pneumonia, after an attack of drinking.

A., an actor, thirty-five years of age, with unknown parentage, consulted me about irregular attacks of inebriety attended with intense depression and suicidal delusions. The paroxysms were preceded by attacks of acute dyspepsia, which came on unexpectedly to him or his friends. He joined the church and many temperance societies, advised with clergymen and others, but obtained no relief; his friends said he was very cheerful, and if his buoyant spirits

could be kept up during the attack of the dyspepsia he would remain temperate, but if from any cause he became depressed, inebriety was inevitable. At times he would determine not to drink, and carry it out; again, he would exhibit the same firmness and energy, yet fall. My advice to stop work and go under physical treatment for this condition was neglected, and today he is alternately reforming and relapsing, seemingly dependent upon obscure unknown conditions.

These cases both exhibited disordered emotional symptoms, and seemed to try hard to recover by the use of the will and the exercise of faith and prayer. They both could, at times, restrain themselves, and were enigmas to their friends. These cases may be termed emotional or accidental inebriates, and follow an apparently erratic, confused course, appearing and disappearing at unexpected times and seasons. A noted temperance lecturer, who is of this class, has a paroxysm of drink craving every two hundred days. At times he is able to resist, at others he gives way, but no matter what the time or circumstances may be, the return of this paroxysm is certain and invariable.

I am sure that a study of these cases will indicate the laws which govern them, and show the same realm of physiological and psychological forces as that which govern other diseases. I protest against calling every symptom that is obscure an evidence of vice, and attempting to reach it by spiritual agencies alone. Because an inebriate, under the emotional excitement of religious or temperance appeals, reforms and remains temperate, to reason that these means will be effectual in all other cases, or that the disorder is simply a vice, is thoroughly unscientific. Cases are found where chronic inebriates reformed at once without any cause, under the most adverse conditions; the same unknown element is seen in all diseases, indicating merely our ignorance of the knowledge and conditions of all the laws governing them. Any careful study of inebriety will show that its complex causation and character cannot be reached by any specific or special methods, and all efforts to cure it as a vice by spiritual means must result in failure. I would not discourage the efforts of church and society, but seek rather to educate them into a broader view on the subject and the use of means adequate to reach the disorder. I would urge upon the profession the study of this subject with a true scientific spirit, and thus seek to teach the enthusiastic church and temperance reformers how to work more effectually and on a broader plane. The profession should teach the world what inebriety is and how to treat it, and not reformed inebriates and clergymen, who are heard in every town of the land. The following conclusions I am sure will be confirmed by all who have had any experience, and are founded on rational natural means:—

1. Inebriety is a physical disease which must be reached by both physical and psychical means.

2. All methods of treatment must be along the line of natural laws, and include all means, both physical and spiritual, that can build up and strengthen the entire man.

3. Spiritual means are only valuable in proportion as they are used with other means, and where they are effectual alone, they are the exception to the rule and cannot indicate any direct line of treatment.

Medical Societies.

KENTUCKY STATE MEDICAL ASSOCIATION.

ANNUAL MEETING.

Reported by A. H. Kelch, M.D.

This, the twenty-sixth annual session of the Kentucky State Medical Society, convened at Covington, on the afternoon of Tuesday, April 5th. At three o'clock Dr. Lyman Beecher Todd, of Lexington, called the meeting to order, and the work of organization at once began. But little time was consumed in listening to the reports of the Secretary and Treasurer, and of the committees of arrangements, entertainments, etc., when the regular order of the reports of papers, according to the programme, was entered upon. The lateness of the hour of opening was necessarily followed by a short session, and but three papers were, in the afternoon, presented. Dr. G. L. Dunlap, of Danville, read an interesting paper on improvements in surgery, being followed by Dr. C. H. Thomas, of Covington, on improvements in the practice of medicine, and Dr. S. M. Letcher on hygiene. The association was then adjourned until eight o'clock in the evening, when it reassembled to hear the President's address, as usual. Dr. Todd is a pleasing speaker, a man of good address, and his oration was well received. He began by saying that "the quarter century anniversary of his professional life has been crowned by the highest honors it was in the power of an association representing a noble State to confer." He uttered his appreciation of this expression of confidence and esteem, and considered it appropriate, in view of the circumstances, to call the attention of the society to a *quarter century retrospect in medicine and what it teaches.* After dwelling at some length upon the nobility and the grandeur of the profession chosen by those who form the membership of the body he was addressing, he said: "You are the representatives of discoveries—the circulation of the blood, auscultation, vaccination,

the ligature, ovariotomy—which will live and bless the world forever. The names of Harvey, Laurence, Jenner, Pare and McDowell are immortal. The historic muse, proud of the charge, marches with them down to succeeding ages, and when the knell of time shall have sounded, they shall live on in the ever widening cycles of eternity." In speaking of anæsthesia, Dr. Todd compared the world to a temple, saying: "Within this temple's grandest hall a statue of matchless beauty stands, the master's noblest conception, art's proudest triumph. From a vase of rare designs, held in her half extended hand, arose a vapor, ethereal, and though unseen by mortal eye, more potent far than perfumed incense from priestly censer ever swung. This thing of beauty stood all veiled, a fitting emblem of that mystic potent spell in which all who approached it soon were bound. From joyous youth to hoary age, from every clime, toward it I behold an innumerable and afflicted throng of human life come crowding, surging on. Upon the features of every face is stamped the trace of pain, and anguish and sorrow; sighs and groans alone escape their lips. In dismal procession the wounded, maimed and crippled, by friendly hands are borne, and children, too, in affection's tireless arms, and not in all this vast concourse a single smile is seen. O! acme of human horror and human sorrow. Whence come they, whither go and why? From every scene of battle, from every field of strife, from every place where injuries may befall, they come, and, passing this figure of wondrous power and mystic spell, they sleep a quiet, peaceful sleep. They disappear to reappear again, but O how changed! Returning, circling round that statue, which now, indeed, seems to smile, in shouts of joy, in strains of wildest, sweetest music, they proclaim peans of victory to science's power. That name is caught and canonized by poetry and history, and shouted by all in rapturous acclaim, "anæsthesia, anæsthesia, anæsthesia, heaven's second best gift to man!"

A fitting tribute next was paid to preventive medicine; the treatment and protection of the insane and prevention of insanity received consideration; the cultivation of specialism in medicine was commended, and the effort to elevate the standard of medical education eulogized. Training schools for nurses were not forgotten, and the speaker closed with a reference to the names of Dudley, Lowry, Bruce, Yandell, Rogers, Jackson; and last, whose career was short, but bright as brief, he spoke "of Cowling, gifted, eloquent, and graceful Cowling, summoned but yesterday to roll call above, when we had hoped to meet him here. His death, blighting high hopes and closing a grand career, saddens your hearts and mine, as now upon his new made grave, with loving hand, I strew spring's earliest roses wreathed with immortelles."

The morning session of Wednesday opened with a very large attendance, and immediately after order was called Dr. Wm. H. Wathen, of Louisville, moved to appoint a committee to draft suitable resolutions commemorating the death of Dr. R. O. Cowling. Dr. Wathen's motion was unanimously adopted, the president appointing him as chairman of the committee on such resolutions. In the course of the morning this committee reported as follows: "Your committee, appointed to report resolutions expressing the sentiments of the Kentucky Medical Society on the announcement of the death of Dr. R. O. Cowling, find the task a very difficult one. All formal phrases are unworthy the occasion. What he was to us, each shall often feel, in thoughts that lie too deep for words. Memory alone can adequately remind us of the cheer we had in his company, and the confidence we put in his counsels. Our sense of immeasurable loss and dissatisfaction at this feeble public indication of it will be duly appreciated by his family, and all others whom a good fortune brought near to him. To them we offer all the comfort they can get from the knowledge that their grief is shared by a large circle of his professional associates." "We suggest that this testimony be spread upon the minutes and properly engrossed for transmission to his family."

Dr. J. J. Speed, in seconding the adoption of the resolution, paid the following tribute to Dr. Cowling: "If genius and fine culture, and unfailing wit—but a wit that never wounded—entitle a fellow man to our admiration, Dr. Cowling was entitled to it, for he had them all. A genial companion, and a man whose opinion older men sought, and before whom younger men bowed as before a shrine, has gone from among us. In the prime of a strong manhood, before most strong men begin to fail, his generous heart, unrecognized even by himself, as a muffled drum, was beating funeral marches to the grave. I said he was a man of genius; his presentation of the McDowell relic to Dr. Gross, at Danville, was, perhaps, the finest piece of oratory that this Society has ever listened to. Whatever comparisons may be made between them as surgeons, he certainly outwrote and outspoke the great Nestor. He has left his mark upon surgery in the west, and it is a fair presumption that, had his life been spared for future labor, he would have ranked with the foremost surgeons on this continent."

After the unanimous adoption of the resolution, the call for irregular business brought Dr. T. N. Wise, of Covington, to the floor, with a resolution to have the proceedings, along with the minutes of the present session, published in pamphlet form. After speaking at some length he was curtly informed by Dr. D. W. Yandell that if he had taken the medical periodicals of the day he would have seen that the matter of the publication of the minutes and proceedings had been definitely settled last year, at Lexington; that the minutes of the meeting only are to be published by the Secretary, and the papers presented to be published through whatever channel their authors might desire; that this forward step by the Kentucky Medical Society had been highly commended by the profession in the States of Texas, Missouri, and Illinois, and therefore the gentleman's resolution could not prevail. Dr. Wise continued by saying that he was a subscriber to the *American Practitioner*, but sometimes found it a difficult matter to read it, and further, that his resolution was intended to apply but to the proceedings of this particular session.

Dr. Dudley S. Reynolds raised the point of order, in which he was sustained by the chair, thus ruling the resolution and the discussion out of order.

Dr. J. H. Letcher, of Henderson, chairman of the committee on improved Constitution and By-laws, was next recognized by the chair, and reported that after carefully examining the constitution and by-laws of the different State Medical Associations, from Massachusetts to Alabama, as a result of his investigations, he had largely drawn the suggestions he had to make from the constitution of the Medical Association of the State of Tennessee.

When the report was read it created considerable discussion. The constitution suggested the requirement of a bond from its officers. Dr. Reynolds called the attention of the Society to the fact that the Association is not an incorporated body, and therefore, cannot require a bond of its officers. He also recommended that the committee consider the propriety of changing the time and place of meeting, so as to make the latter central and unchangeable and the former to suit the convenience of busy practitioners throughout the State. He also suggested that since the proceedings were no longer to be published in pamphlet form, three dollars annual dues is more than is necessary, and he thought that two dollars would be quite sufficient. He then moved to refer the report back to the committee, to be revised by it and the nominating committee, in joint session, and this motion being carried, the report came back, having very briefly stated the following propositions different from the constitution at present in force. "That aside from permanent and honorary members there shall be *delegated* members from the local societies, both city and county, one for each five members of each society, and one for each fraction over five, these delegated members becoming permanent members, so long as they conform to the rules and regulations of the Society. This article also provides that officers of the State Society, and chairmen of all committees of reports shall be delegates *ex officio*. Provision is also made for a permanent Recording Secretary. It abolishes the Publication Committee, and hence the publication of the papers read before the Society, and makes it the duty of the permanent Secretary to have printed and sent to each member of the Society the minutes of each annual meeting, together with reports of the several officers of the Society and the Committee on Finance only. It also provides that none but delegates and permanent members in actual attendance shall be eligible to any of the offices of the Society or as delegates to the American Medical Association, or State medical societies. It makes certain rules and regulations in regard to all city and county societies which shall be auxiliary to the State Society. Provides for the division of the State into twelve censorial districts, a Board of Censors for each district being elected by the State Society and each county in the State being represented by one physician in the Board. The Board of censors for each district shall examine all laws and regulations of the local societies in their respective districts, decide all cases of appeal from aggrieved members of local societies, decide all questions pertaining to the code of ethics, etc. It also provides for the raising of a "Prize Essay Fund," which shall be devoted to the payment of a prize for the best essay on some designated subject, the decision to be made by a Prize Essay Committee. It provides that the permanent place of meeting shall be in Louisville, at the rooms of the Polytechnic Society of Kentucky, that the time of meeting shall be the first Wednesday in April, and that the annual dues shall be $2.00.

This question having been disposed of, Dr. Dudley S. Reynolds brought up the subject of reforms in medical teaching, saying that, inasmuch as at the last meeting of the Medical College Association a resolution was adopted, making it incumbent upon members to require of applicants for graduation an attendance upon three full courses of lectures, and that in view of the action of some of the eastern colleges, notably the College of Physicians and Surgeons and the Bellevue Hospital Medical College, of New York, in withdrawing from such a contest for purely mercenary considerations, after promising to abide by such arrangement, he thought it proper that the various State societies should take some action, or give some expression of the feeling of the profession outside of the medical colleges, and he therefore offered the following:—

"*Resolved*, That it is the judgment of the Kentucky State Medical Society that the American Medical College Association should be encouraged in the attempt it has been making to institute reforms in the method of medical teaching, and we pledge it our hearty support."

This resolution was unanimously adopted.

Dr. W. W. Dawson, of Cincinnati, having made his appearance in the audience, was, by a vote of the Society, made a corresponding member, and was invited to a seat on the platform.

Dr. McCormack, of Bowling Green, presented for the consideration of the Society an amendment to the present law regulating the practice of medicine in Kentucky. The amendment proposed is to read thus: "And any person who is now practicing, or may hereafter propose to practice, in any way whatever, in any county in this Commonwealth, shall first appear before the judge of the County Court of such county and exhibit to him a diploma from a regularly chartered medical college, or a certificate of qualification from a District Board of Medical Examiners of this State, or satisfactory evidence that such person has been regularly and continuously engaged in the practice of medicine in this State for ten years prior to the passage of the law of which this is an amendment. Such person shall also make affidavit that he is the person named in the diploma or certificate, and how long and where he has been located.

"It shall be the duty of the County Judge before whom the exhibit and affidavit are made to give to such person a certificate setting forth the name of the college or board issuing the diploma or certificate, date of certificate or diploma and such other facts as are contained in the affidavit which shall be furnished by him to the County Clerk of such county, for record in a

book kept by him for that purpose, which shall be open to the inspection of the public at all times. And it is hereby provided, that a regularly chartered Medical College, within the meaning of this act, is one reputably engaged in teaching the science of medicine, as recognized by the school or system of medicine to which it professes to belong, and that a board of examiners, within the meaning of this act, is one of the legally organized boards of medical examiners of this State. It is hereby made the duty of the State Board of Health of this State to prepare a list of such colleges and boards, and furnish such list to each of the County Judges of this State, and that such list shall be the sole guide of such judges in determining the standing of medical colleges and examining boards.

"It is hereby made the duty of the County Boards of Health to report violations of this law to the Grand Juries of their respective districts.

"Any person violating this act shall be subject to all the penalties prescribed by the original act, of which this is an amendment."

This amendment was unanimously endorsed by the Society, and it was voted to present a copy of the same to the committee on hygiene and sanitation, of the next legislature, with the recommendation of the Society for its passage.

While the business of the Association was being transacted, the annual meeting of the Board of Health was held, and they reported, through their secretary, that their meeting was a very satisfactory one. That some progress has been made by placing in the hands of every doctor in the State a blank book for returns of births, marriages and deaths, by securing a list of 2500 names of doctors, with their post office addresses, and by sending copies of their annual report to every publication in the State. The attention of physicians has been called to the necessity for coöperation in order to secure any satisfactory results. The next meeting of the Board will be held in Hopkinsville, July 1st, and delegates are to be sent to attend the Mississippi Valley Sanitary Association, held at Evansville, Ind., on the 20th of this month.

Dr. McCormack moved to recommend to the legislature, at its next session, the application of a law relating to the qualification of druggists and pharmacists in cities, to druggists and dispensers of medicine in general throughout the State. This has reference to a law passed in 1874, which provides that all druggists and dispensers of medicines in corporations of 5000 and upward must be graduates in pharmacy.

Dr. J. W. Holland, of Louisville, was recommended by the nominating committee for President; Dr. Chas. Mann, of Nicholasville, Senior Vice-President; Dr. C. H. Thomas, of Covington, Junior Vice-President; Dr. L. S. McMurtrie, of Danville, for permanent Recording Secretary; Dr. J. N. McCormack, of Bowling Green, for Corresponding Secretary; Dudley S. Reynolds, M.D., Chairman; W. O. Roberts, M.D., and J. A. Ireland, M.D., the Committee on Publication; all of whom were unanimously elected by the Society. The President nominated the following committee on prize essays, which on motion was confirmed by the Society. Dudley S. Reynolds, M.D., Chairman; David W. Yandell, M.D., Louisville; A. R. McKee, M.D., Danville; H. M. Skillman, M.D., Lexington; Chas. H. Todd, M.D., Owensboro. The president then appointed the chairman of the committee of arrangements for next meeting, appointing Dr. Dudley S. Reynolds, of Louisville.

Twenty-five delegates to the American Medical Association were appointed; Drs. Dawson, Whittaker and Dandridge, of Cincinnati, were elected corresponding members, and with returning votes of thanks to almost every one and every thing, the business portion of the meeting closed.

The following is a summary of the literary features of the meeting.

Dr. J. W. Holland read a paper on the subject of chronic poisoning from the use of cosmetics. He said his object was to call attention to the fact that lead poisoning has certain vague but interesting features different from those of wrist drop and colic, and that a case may continue to complete saturation of the system without the remarkable sign of wrist drop being presented at any time. In proof of which he related the case of a young lady who came to him complaining of symptoms of constitutional weakness, dyspepsia, falling of the hair, and having yellowness of the sclerotic and a general cachectic state. She presented at this time the unmistakable evidences of lead poisoning in the existence of double drop-wrist and the blue line along the gums. This young woman had been strong and hearty until two years previous to the time when she came under observation, at which time she began to use flake white. Her history since has been an interesting sketch of vertigo, headache, recurring attacks of colic, constipation and dyspepsia, her general health gradually but surely declining, until a short time since she suffered from attacks of melancholic mania, which lasted for a month. The case had repeatedly baffled the skill of practitioners, and a singular feature about it was the improvement which resulted from confinement to the house. Under these circumstances, the cosmetic being unapplied, the system relieved itself, to some extent, of the poison. She was wholly ignorant of the cause of her condition until the wrist drop drew attention to the specific nature of the poison. "On her second visit to me," says Dr. Holland, "she was accompanied by her sister, a seamstress, who had been compelled to quit work on account of failure of strength in the arms. She had been using the same preparation for the same length of time, and had suffered from the lead gout, as it is called, and from what was presumed to be epileptic convulsions." He emphasized the two facts which it was the object of his paper to call attention to, namely, that lead may be introduced into the system from absorption through the skin, when applied in the form of cosmetic powders, enamel lotions, or in the form of what are called hair restorers; secondly, that the most beautifying enamels are composed of white lead, and that nearly all hair restorers contain sugar of lead.

Dr. Wathen related a similar experience, in which a young lady consulted him, and was treated by him, for irregularities of menstruation,

until the multiplicity and diversity of symptoms caused a close investigation of the case, when it was revealed that she had been applying cosmetics to a sufficient extent to obscure the freckles on her face.

Dr. M. T. Scott, of Lexington, who had been appointed to read a paper on the diagnosis of diseases of the chest, announced that he would confine himself to the consideration of an obscure case of aneurism of the thoracic aorta, with remarks on its diagnosis. The patient was a brick mason, colored, forty-seven years old; came under observation February 29th, 1880. For a year he had suffered from vague and anomalous symptoms referable to the thoracic and abdominal organs; his principal complaint being of dyspnœa, almost constant, never excessive, and little if at all increased by exertion. Periodically, he complained of a dull, gnawing pain, of a neuralgic character; this was worse at night. He had a syphilitic history, symptoms of exophthalmic goitre were present, and the countenance was expressive of anxiety and pain. The lungs were emphysematous, percussion note vesiculotympanitic, cardiac dullness decreased, but the heart sounds normal, pulse from 100 to 125, and temperature always below 100° F. No thrill, murmur, bruit. or localized bulging, even, was manifested. The dull boring pain between the spine and left scapula became more and more intense as the case progressed to a fatal termination, which occurred suddenly, during a paroxysm of coughing. The autopsy revealed an aneurism the size of a large orange, at the upper portion of the thoracic aorta. This condition existed as a dilatation of the coats of the vessel. The normal calibre of the vessel terminated abruptly at both the proximal and the distal sides of the sac. The bodies of the 3d, 4th, 5th, and 6th dorsal vertebræ were eroded, and the rupture of the sac had allowed the blood to escape into the left bronchus. Dr. Scott then entered into a discussion of the case at some length, citing statistics as to the frequency of occurrence of aneurism in the various portions of the aorta. He then referred to a variety of conditions that may affect the calibre of intra-thoracic vessels, thus causing murmurs and capable of misleading, and reached, as the final proposition, that, after all, we are indeed compelled to rely for our diagnosis upon the indirect symptoms, the sequential phenomena.

Dr. J. D. Neet, of Versailles, reported an obscure and interesting case of pyothorax, which occurred in an individual free from any history of hereditary tuberculosis. The individual, throughout the period of his illness, had an excellent appetite, and would have been well nourished but for the constant drain of pus from openings, spontaneous in character, increasing both in size and number as the case progressed. The autopsy revealed no sign of tubercle, nor of fibroid phthisis, and Dr. Neet rather favored the opinion of death by exhaustion, being seemingly unable to further account for the pathological condition.

Dr. Whittaker, of Cincinnati, regarded it as a case of "empyema necessitatis," and considered the case undoubtedly tuberculous in character, notwithstanding the history. He held that tuberculosis is first a blood disease, and as such it is more frequently acquired than inherited. He then made some remarks concerning the generation of pus from the white blood corpuscle, through the transformation of the cell by its death.

Dr. A. M. Vance read a paper on the "removable paper brace in the treatment of spinal curvature." At the conclusion of his paper, Dr. Dawson, of Cincinnati, and Dr. Yandell, of Louisville, engaged in a somewhat lengthy, though interesting discussion of the merits of various dressings in spinal diseases, the general agreement seeming to be that the acme of perfection is not yet reached in this respect. A desire was repeatedly expressed for the invention of a flexible and easily adjusted dressing, which, while it permits of freedom of motion and ready adaptation, yet does not lose sight of the prime object of all such dressings, which is to give unyielding support and absolute rest to the afflicted portions.

Dr. Harwood, of Shelbyville, read a report on the therapeutic uses of quinine, in which he took the ground that when given to the extent of twenty grains a day, in cases of remittent fever, or intermittent when the apyrexia is short, it will produce the increase of temperature which it is an object in the treatment to abate. He has no doubt that many cases of relapse, as it is understood to be in these cases, are cases in which the action of the drug is not understood, or, being known, is disregarded.

Dr. Dunlap made a report on the epidemic and contagious diseases of central Kentucky from which it appears that a few cases of measles and now and then a case of scarlet fever is about all the wave of trouble of this kind that has rolled across the peaceful breast of the State.

Dr. W. O. Roberts reported a case of successful ovariotomy, exhibiting the specimen, and called attention to the fact that, performed under strictly antiseptic precautions, the case was afterwards troubled by comparatively no rise of temperature, and under the use of hypodermic morphia, as an anodyne, recovered entirely in the course of two weeks.

Dr. Coomes, of Louisville, being unable to attend the Society, had his report read. It consisted in the description of what might be called an audiometer. He claims that by its use malingerers may at once be detected, while the instrument serves the purpose of both measuring the acuteness of hearing and registering any improvement that may take place from day to day, as well as permitting the operator to test the patient's hearing with reference to different sounds, from musical tones to conversation.

Dr. Wathen presented some ideas upon the subject of urethral examination in females, detailing the unsatisfactory methods that have previously been practiced, and calling attention to the general desire for some improvement in this direction. He thinks much may be accomplished by the application of a *modified dilating forceps* to these cases, provided the instrument be properly manipulated.

Dr. McMurtrie read a report on the subject of typhoid fever.

Taken all in all the policy of the meeting just

ended has been of more importance than its literary accomplishments. While the latter have been fair, the work done this year, in the matter of business, is, no doubt, destined to have much influence upon the attitude which the profession shall assume in this State in the future.

Periscope.

The Pathology and Treatment of Sea-sickness.

Dr. O. G. Wood writes to the *British Medical Journal*, on the subject of sea sickness:—

My experience leads me to the following general conclusions:

1. Individuals who cannot look down from a height without feeling giddy suffer more frequently and more persistently than those who do not experience such sensations.

2. Men who are accustomed to smoke strong tobacco suffer less frequently and recover sooner than non smokers or those who use mild mixtures.

3. The people who suffer least (leaving out of consideration those who, from habit, or early training, have become accustomed to the motion of a ship) are men of naturally "strong heads" and "good nerve" expressive, if not strictly scientific terms); men of good physical development, who ride straight, delight in games requiring both pluck and judgment, and never lose their presence of mind in any emergency. Hence, perhaps, the reason why sea-sickness has from time immemorial been considered a fair subject for ridicule, as implying a certain deficiency in the manly virtues.

4. Sea sickness supervenes sooner on an empty stomach, and when a "bad sailor" has recovered from sea sickness he often continues to suffer from nausea on first rising in the morning; that is to say, in the long fast between dinner and breakfast, and on changing the recumbent for the upright position.

5. If stimulants (among which I include small doses of opium) be taken while in the recumbent posture, and retained by the stomach, a temporary power of resisting sea sickness is obtained, but a very pronounced reaction, not easily remedied, is apt to follow this alleviation.

6. It is exceptional to find a woman who is really a "good sailor."

To each of these propositions, more particularly the last, there are undoubtedly exceptions; but to my own mind there are sufficient data on which to base the following conclusions:—

1. There is analogy between sea sickness and the feeling of nausea often produced by fear or other disturbing mental emotions.

2. Sea-sickness is, in the first instance, at least, a purely cerebral phenomenon, though doubtless the repeated acts of vomiting do in time produce local gastric irritability.

3. This cerebral phenomenon is due to the disordered (irregular?) intra-cranial circulation, which, produced at first by the motion of the ship, is maintained and intensified by a secondary disturbance of the normal inhibitory function of the vagus causing a rapid, weaker, and irregular action of the heart. Hence, the effect of the recumbent posture, and, perhaps, in part, the influence of stimulants.

If, then, my views be correct, the indication for the treatment of this truly distressing malady is to regulate the cerebral circulation; and this I would attempt to do the moment the first sense of nausea began to manifest itself. I fear we shall never be able therapeutically to prevent sea sickness, but I do hope that we may some day be able to cure it. The next sea-voyage I have to make, I intend to take with me the following mixture, and to try the effect of a one ounce dose twice a day:—

℞.	Liquoris atropiæ,		♏xij
	Tincturæ digitalis,		♏lxxx
	Tincturæ cannabis indicæ,		♏xl
	Tincturæ capsici,		f. ʒ ij
	Olei caryophylli,		♏xvj
	Lymph. aurantii,		
	Mucilaginis acaciæ,	āā	f. ʒ j
	Aquæ,	ad	f. ʒ viij. M.

At the same time, of course, carefully regulating the bowels, which are apt to become constipated on a sea-voyage. I am inclined to believe that the combined action of atropine and digitalis, together with the slightly exhilarating effect of the Indian hemp, may enable us to meet the indication to which I have already referred.

Transmission of Rabies by Inoculation.

In the month of January M. Maurice Reynaud read a communication on this subject before the French Academy of Medicine.

A child died at the Trousseau Hospital (Paris), of confirmed hydrophobia; just before its death four rabbits were inoculated with saliva from the mouth of the patient, and three died; two were inoculated with the blood, without fatal result. After the death of the child, two rabbits were inoculated with the mucus found in the bronchial tubes, and both died; six with fragments of the salivary glands, with but one death; the roots of the tri-splanchnic nerve placed under the skin of another rabbit caused death in three days.

In a third series of experiments it was found that the saliva or blood of any one of the animals thus killed invariably caused the death of other rabbits inoculated with it. M. Reynaud concluded from these facts that the transmission of rabies from the human subject to animals was possible, and that these animals died of hydrophobia.

This supposition was contested by M. Colin,

of Alfort, who considered that septicæmia was the cause of death.

M. Pasteur removed some saliva from the mouth of the child, four hours after death, and with it inoculated two rabbits; both perished in thirty-six hours, and their saliva caused the death of two others. In the blood of these animals M. Pasteur discovered a microscopic organism (microbe en huit de chiffre), which differed notably from the vibrion found in septic conditions.

The lack of any period of incubation would seem to be against the supposition regarding the transmission of rabies.

The Academy appointed a commission to experiment on the subject, and M Villemin presented their report (*Concours Méd.*, Feb. 19th). In a first series of experiments, two rabbits were inoculated with a drop of septic blood and died in less than twenty four hours. At the autopsy, violent local inflammation, serous suffusion, profound alteration of the tissues, softened spleen, numerous bacilli (microbes en batonnets) in the serous fluid, infiltrating the tissues, but none in the blood taken from the heart.

2. Two rabbits were inoculated with a drop of blood obtained from the animals which had been inoculated with the child's saliva; they succumbed, one in eighteen, the other in thirty-six hours. Autopsy: turgescence of venous system; induration of the spleen; spots and hemorrhagic suffusion in trachea and lungs; finally bacilli of figure of eight shape (microbes en huit de chiffre) in the blood, differing essentially from the vibrions proper to septicæmia found in the other case.

The conclusion arrived at by the commission was that it was impossible to consider this disease identical with septicæmia.

Incision in Purulent Pericarditis.

An extraordinary and interesting case is recorded in the *Berliner Klin. Wochenschrift*, No. 5, 1881. A boy, ten years of age, suffered from empyema and purulent pericarditis. The pleura was accordingly tapped, and thirty-eight ounces of serous effusion were withdrawn. The pericardium was tapped, and about four ounces of pus taken out. The patient's condition did not much improve; there was very considerable and increasing dyspnœa, with lividity, and some œdema of the feet and legs; sleep was much broken, and the general condition very low. Under the circumstances, it was determined to incise the pericardium, as the physical signs pointed pretty conclusively to a further accumulation of fluid within it. The operation was carried out under the strictest antiseptic precautions. An incision, about three centimetres long, was made between the fourth and fifth ribs, close to the left margin of the sternum, and each layer separately divided until the pericardium was reached. An opening was then made into it, through which a considerable quantity of pus escaped; two drainage tubes were put in, and the wound dressed after Lister's method. The patient was, very shortly after the operation, able to lie on his back, and felt much relieved by it. It was not, however, until at least two hours later that the pulse became appreciable. On the day following the temperature stood at 101° Fahr., but it then came down to normal and remained so. At the end of eight weeks the pericardial wound, which had been gradually closing, was cicatrized. There were no further pericardial troubles. But the signs of the pleuritic effusion pointed to a fresh collection in this cavity, while there was still fever after removing thirty-five ounces of fluid; as the general condition therefore was not relieved, a free incision was made into the chest, and another fifty ounces were removed. Improvement now set in, and at the end of six weeks the wound had closed, and the patient was sent out of the hospital cured.

The author draws the following conclusions from his case: 1. The case teaches that purulent pericarditis, just as empyema, may at times run its course without giving rise to fever or œdema of the tissue, so that the nature of the exudation can only be decided after an exploratory puncture. 2. We must not abstain from removing the exudation on account of any supposed myocarditic changes. 3. In cases of considerable pericardial effusions, change of position may not influence the line of dullness; but this fact must not always be interpreted in favor of dilatation of the heart.

Prognosis in Cardiac Disease.

At a meeting of the Medical Society of London, in February, Dr. Milner Fothergill read a paper on the "Prospects of Cases of Valvular Disease of the Heart." He pointed out that the well marked cases, as described in text-books, were generally recognized and appraised correctly. But there were other cases marked by the presence of a murmur; when the prospect was very much better. Much misery to patients, and considerable discredit to the profession, were the result of transferring to such cases the prognosis of the most serious forms. Practitioners scarcely ever erred about the grave cases, but they were not always so accurate about the less serious cases. Stokes long ago pointed out that there were cases where the mischief did not progress, or imperceptibly; and Latham differentiated three forms of mitral mischief after endocarditis of varying severity. It was important to recognize the fact that in many cases the injury done is quiescent, like a scar, and the patient is only conscious of something wrong on effort. All light work was not incompatible with length of days. He then related the history of four cases, all well known to him, of mitral disease.

1. A girl who had a loud mitral murmur at the age of eight. She is now twenty-four, in fair health, as a village schoolmistress.

2. A man whose murmur was first heard in 1867, sometimes ailing, but at work as a blacksmith, only troubled when shoeing very heavy horses.

3. His sister, with disease of two years' standing, last year flooded in labor. She became anæmic, and then some dropsy followed, which quite disappeared under treatment.

4. A man with some mitral disease, of twenty-seven years' standing, who had dropsy for the first time last autumn, after a short illness. He is now free from any dropsy and feeling well

again. Another case of severe mitral disease, lasting thirty-eight years, was cut short by bronchitis last spring. Even aortic regurgitation does not always progress rapidly, and he knew of a number of cases where no perceptible progress had been made in four or five years. Consequently we are not to take a hopeless view of all cases of valvular disease of the heart.

On the Control of Diarrhœa in Typhoid Fever.

Dr. James W. Allan, superintendent of the Glasgow Fever Hospital, says, in the *Lancet*, March 19:—

It is, perhaps, better not to attempt to check the diarrhœa of enteric fever so long as it is mild—that is to say, as long as the motions do not exceed three or four in the twenty-four hours. But when the stools are very loose and copious, as well as frequent, it becomes a very desirable thing to control, if not to stop, the diarrhœa. Severe purging rapidly exhausts a patient. In the case of children the following measures may be tried:—(1) Boiling the milk which constitutes patient's diet; (2) boiling cinnamon in the milk, and straining it; (3) adding lime-water to the milk in varying proportions, say from one in four to half and half.

The above simple remedies are well worthy of trial. They have the great advantage, in the case of children, of not being "bad to take," and further, while the patient is taking the medicine he is taking his diet (*i. e.*, milk) at the same time.

In the case of adults the means just mentioned should first of all have a trial. If they fail we may then try (1) that excellent pill—lead pill with opium—say one every three or four hours, till the diarrhœa is restrained. This pill is very valuable in the treatment of purging, and it has the additional advantage of tending to relieve pain and check flatulent distention of the intestines. Should the purging continue, and especially if the desire to go to stool be urgent and persistent, we should at once resort (2) to the use of the starch and laudanum injection—say ten, fifteen or twenty drops of laudanum in two tablespoonfuls of thick starch, injected into the rectum. This is a capital remedy; it checks the diarrhœa, allays the irritation, and probably at the same time disposes the patient to sleep. It is perhaps unnecessary to add, that no beef-tea should be given while there is diarrhœa.

Prevention of the Irritating Effects of Atropia.

In the Cincinnati *Lancet and Clinic*, Dr. W. W. Seely, writes:—

It is well known that atropia not unfrequently causes even a vast amount of irritation to the conjunctiva, so great in some cases as to preclude its use.

The suggestion made by myself in 1867, of combining a small quantity of some astringent (usually zinc) with the atropia has remained the only practical solution of the difficulty, and has probably been used by everybody.

Since the well known effect of eserine of contracting blood vessels has been recognized, combining a quantity with the atropia has been tried, and with a certain degree of satisfaction; but the fundamental action of these two substances, as all know, is the opposite, so the eserine detracts somewhat from the mydriatic effect of the atropia, an effect whose diminution can be poorly tolerated, since in iritis (about the only territory left for atropia) we want the greatest possible mydriatic results.

Now, it is surprising what a controlling effect the yellow oxide of mercury has over exactly the state produced by the atropia, and I am in the habit of using it daily in cases of iritis, with apparently the most satisfactory results, quite perfectly overcoming any irritation from the atropine. My experience has not been conclusive, so far as this irritating effect of atropia goes, simply because I have encountered no excessive irritation from the atropia, and hence simply suggest this remedy for trial.

As regards the direct benefit over the iritis, by controlling the calibre of the anterior ciliary arteries, I am not certain but that some benefit may accrue by the use of the yellow oxide, or some other remedy that will diminish the size of these vessels.

Death from Swallowing False Teeth.

The following curious case is reported by J. H. Gardiner, M.D., in the *Canada Journal of Medical Science*, March, 1881:—

On Jan. 20th, 1881, Mrs. B., æt. 33, was supping some soup, when a plate and two false teeth attached became loosened and slipped down her throat. Violent retching followed, lasting for several hours, but was finally allayed, whether from the stomach becoming accustomed to the foreign body, or from bismuth freely administered, I do not know. A dull, heavy pain was complained of over epigastrium and in the back over region of stomach, which remained until death. The retching at times recurred, but only slightly. A difficulty in swallowing was complained of, even liquids causing pain. I ordered her to remain in bed, and to take bread and milk, corn starch, or any fluid or mucilaginous food. My instructions were not followed; but the patient persisted in being around and doing her usual "housework." Just one week after the accident happened the patient was seized with violent hæmatemesis, accompanied with purging. Dr. Charles Moore, Sr., saw the case with me, and we agreed as to the cause of the hemorrhage, viz., the severing of one of the arteries of the stomach. Ergotin was used hypodermically in eight grain doses every three hours. All efforts of treatment by the mouth only aggravated the symptoms. The vomiting soon ceased, but the purging continued until the end; and seventeen hours after the appearance of the first urgent symptoms the patient died. In the absence of an autopsy, I can only say that I think the accident was caused by a sharp angle of the plate, which was broken previously, being caught in a fold of the stomach near the cardiac orifice, and this had severed one of the arteries of the stomach.

The Relation of Brain Substance to Mental Power.

In the *Canada Journal of Medicine*, March, 1881, Dr. Daniel Clark collects a large number of instances where, after most severe lesions of the brain, little or no motor impairment followed. The inference he draws is as follows:—

These examples might be indefinitely extended. Medical literature is full of evidences of destruction to the brain matter of the cerebrum and cerebellum, without any serious impairment of mental power or physical functions. Let a brain be taken, and wires passed through it to indicate the course of the missiles in these cases I have mentioned, and it will be seen that brain substance has been injured in almost every conceivable direction, yet with no results at all commensurate with the lesions inflicted. If these parts are motor centres, then have we the miraculous phenomena of organic operations without an organ; of varied and distinct functions without a motive power; of uniform results without an efficient cause. Were we even to consider the brain a dual organ, the difficulty would remain, where corresponding sides are simultaneously injured. In all the dual organs of the body we find sudden injury to one is always followed by imperfect work in its fellow, until time is given to allow provision to be made for the extra labor imposed. When we find no impairment in function consequent on destruction of *one* so-called motor centre, we are led by uniform analogy to doubt a doctrine so anomalous and contradictory. At least, it is better to receive with caution a theory which is being accepted, based upon exceptional examples, which do not account for the physical results, except in isolated cases. The mental effects seen, as consequent upon brain injury, would prove too prolific a theme for present investigation.

The Cold Treatment of Dysentery.

The treatment of dysentery by enemata of ice water is not new in this country, but the recent trial of it by Dr. Mich elov, of St. Petersburg, as quoted in the London *Medical Record*, is not without interest. He says it has not failed him in a single case for four years. It proved especially successful in the cases of his own children. A short description of two cases follows. Quinine, in the form of Botkin's cholera drops, was administered internally in all cases. (Compound tincture of quinine, Hoffman's anodyne spirit, of each half an ounce; hydrochlorate of quinine, one scruple; dilute hydrochloric acid, half a drachm; tincture of opium, half a drachm; peppermint oil, fifteen drops.) The diet consisted of *bouillon*, milk, and eggs; the drink was cold water and red wine. The enemata were made in the following manner: Ice was crushed to paste; from this mass of ice two glasses were taken for grown-up men for every enema; for children, according to age, beginning with half a glassful, and so on. Water was then added while the ice floated. It was then poured into a glass funnel connected with a long tube. This funnel, fixed on a stand, remained near the sick bed; in other words, the apparatus remained in action until the mass of ice melted and flowed slowly into the rectum, which process lasted about one or one and a half hours. The enemata were employed every two hours, then every three and four hours; finally, twice or three times daily. The author succeeded in all cases in curing the disease in eight or ten days.

Bronzing of the Skin.

A curious case was presented to the Clinical Society of London, last month, by Dr. R. Crocker. The patient was a sailor, and a native of North Sweden, aged twenty-two, stoutly built, and in good health; and the pigmentation came on after exposure to severe weather eight years ago, attained its full development in a few days, and has not extended or diminished since the first week, though he thinks he is paler at some times than at others. The hands, backs of the forearms, legs below the knee, and mucous membrane, are unaffected, but all the rest of the body is darker. The pigmentation had no sharp line of demarcation on the limbs and face, shading off to the normal. The general line was a yellowish brown, but the neck, axillæ, nipples, umbilicus, penis and scrotum, were black. The abdomen, bend of elbow, and interscapular region were somewhat darker than the general line; while the face and limbs generally were paler. On the face the forehead was most affected. On the neck and axillæ were closely aggregated papillary growths, about one eighth of an inch long, and the natural lines of the skin everywhere were deepened. Repeated alkaline baths and friction had no effect upon the discoloration. Microscopical examination of the skin of the abdomen showed the pigment to be deposited in the deepest cells of the rete, though pigment granules were to be seen both in the layers and in and about the papillary vessels of the corium. The corneous layer encroached upon the interpapillary part of the rete mucosum, so that that part formed a narrow layer of uniform thickness moulded upon the papillæ; these were elongated apparently by the protrusion downward of the interpapillary processes. The papillary growths upon the neck consisted of an outgrowth of the papillary layer of the corium, involving several elongated papillæ. The pigment was in the same position as elsewhere, but there was no alteration in the arrangement of the epidermic layers. Dr. Crocker was unable to offer any satisfactory explanation of the pathology of this condition, but negatived the idea of its being due to phtheiriasis.

Water Diet in Typhoid Fever.

M. Luton, of Rheims, in the *Jour. de Thérapeutique*, quoted in the London *Medical Record*, gives an account of the manner in which, since 1869, he has been in the habit of using water diet in the treatment of typhoid fever. It is understood that the disease should be taken at its commencement, the diagnosis being well and thoroughly made out. Generally, the patient has been purged and the bowels are acting fairly. The patient is then submitted to a strict diet; the only drink he takes is water, well filtered, if necessary, cooled with ice; and of this he may

drink as much as he likes. At first the patient drinks the water with avidity, then in moderation, and finally with a certain satiety. Sometimes it is vomited at first, but is soon tolerated by the stomach. Under its influence the motions are at first more abundant, then they become more moderate and less fetid, and finally cease, to give place to constipation, which, however, is efficiently combated by injections of cold water only. M. Luton holds that the appearance of the cutaneous red spots marks the culminating point of the disease, after which the period of decrudescence and remission commences. Alimentation may then be commenced, light and careful feeding, composed of milk, especially ass's or mare's milk, or cow's milk diluted with water, if the two former kinds are not to be had; then the rest of the diet of the same character, according to the capability of the patient. According to M. Luton, the synthetic treatment of typhoid fever may be summarized as follows: 1. To furnish to the physiological vaporization, which regulates the temperature of the body, a sufficient amount of material, viz., water. 2. By the dearth of ternary aliments, and generally by a spare diet, to hinder septic fermentations. 3. To induce as far as possible a special antiseptic action, which helps in the purification of the infected economy, and removes the unfavorable chances of an evolution abandoned to its free course. 4. To destroy the germ.

Olive Oil in Gall Stones.

Further evidence of the value of large doses of olive oil as a solvent in gall stones is adduced by Dr. Kennedy, in the *Canada Lancet*, March, 1881. He writes:—

I have already said that should the theory of the separation of the solid from the fluid parts of the oil prove to be the true way of accounting for the formation of the fatty concretions, in that case it is fair to hold that the calculi were not partially, but wholly dissolved. What are the grounds? Undoubted relief was obtained from the symptoms of the presence of gall stones, and the periodical suffering, which in some cases had been of several years' standing, disappeared. Olive oil, the agent employed, is probably the most effective and rapid solvent of cholesterine of any which have hitherto been tried.

As to the *modus operandi* of the agent, let it be considered for a moment how the calculi have in the first instance been formed. Cholesterine, we will say, exists in the blood, and in the liver normally in a fluid state, but in minute quantity. In certain abnormal conditions it is formed in excess, and when so formed it tends to become solid and attach itself to floating shreds of inspissated gall or mucus. The process of the formation of a gall stone has commenced, and layer upon layer of cholesterine being deposited, a gall stone is the result. The reverse of this procedure must take place when a calculus becomes dissolved. If an excess of a material which has the property of dissolving cholesterine be now formed in the blood, and through it into the liver, we have the necessary condition for producing this result. Oleine, if it be so assimilated, furnishes the required condition. That the result does take place in a given instance, can only be arrived at by the subsequent history of the case.

Herpes Gestationis.

At a recent meeting of the Dublin Obstetrical Society, Dr. Walter Smith communicated a paper on this subject, and read the details of a case which had come under his care in June, 1880. Mrs. F., a fisherman's wife, aged 35, who had been married for thirteen years, and had been pregnant nine times, having had two miscarriages, the remaining seven being full-time pregnancies, stated that, five years previously, when six months pregnant of her third child, a rash similar to that for which she now sought advice had made its appearance, commencing at the umbilicus, and continued until two months after delivery, when it gradually subsided, uninfluenced apparently by medical treatment. From that time until October, 1879, when three months pregnant of her seventh child, she was free from skin disease of any kind. At that time an eruption, answering exactly to her description of the former one, appeared around the umbilicus, commencing as a cluster of small vesicles, which rapidly extended over the legs, arms and chin. Within a week after parturition the disease evinced a marked increase of activity, and spread over the abdomen and chest; some large bullæ also formed, as large as a sixpenny piece, containing clear alkaline fluid. The affection gradually decreased after that until a few weeks ago, when she had a relapse. The eruption did not at any time simulate eczema, but looked in many particulars like herpes zoster; but it followed no regular nerve distribution. The scars left by patches which had healed were pigmented. The case Dr. Smith considered interesting, from its great rarity, only about fifteen cases having been placed on record since the year 1840, when it seems first to have been recognized as a distinct affection.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In the April number of the *Penn Monthly*, Dr. Thomas S. Sozinskey has a closely argued article going to show that mortality statistics do not reflect the local sanitary condition of the place from which they are drawn, "and that it is simply absurd to compare aggregate death rates of different places." His reasoning on this subject merits the attention of statisticians.

——Dr. W. G. A. Bonwill, of Philadelphia, in a reprint from the *Scientific American*, gives a full account of the analgesic method of rapid breathing, to which his name is sometimes applied. Those who would become acquainted with this plan in its practical applications, would do well to secure a copy of this little pam-

phlet from the publication office of the *Scientific American*, New York city.

BOOK NOTICES.

Lectures on Diseases of the Nervous System; Especially in Women. By S. Weir Mitchell, M.D., etc. Philadelphia: H. C. Lea's Son & Co. 1881. Cloth, 8vo, pp. 238.

This volume consists of thirteen lectures, dealing chiefly with some of the rarer forms of nervous maladies, and drawn from the author's original observations and investigations. Some of these subjects are as follows: hysterical paralysis and paresis, hysterical aphonia, disorders of sleep and of the gastro-intestinal and respiratory functions in hysterical persons, the mimicry of disease in the hysterical state, unusual spasmodic affections, chorea of childhood and habit chorea, etc. The last chapter is upon the treatment of obstinate cases of nervous exhaustion and hysteria by seclusion, rest, massage, electricity and full feeding. The author here gives the result of his further observations on the employment of the measures he formerly recommended, in his remarkable work on "Fat and Blood, and How to Make Them."

It is needless to say that these lectures are extraordinarily rich in acute observation and sound instruction. The reputation of the author is a guarantee of that, and no reader will be disappointed. Nor can too much be said in praise of the admirable style in which the themes are presented. Dr. Mitchell is a literateur of celebrity outside of his medical writings, and each of these lectures reads with the finished grace of a polished essay.

The lecture on chorea of childhood probably embodies the most interesting original studies. It is illustrated by fine plates, showing its seasonal and meteorological relations. The question in reference to race liability is discussed from the reports of over two hundred physicians in different parts of the South.

In the chapters on the mimicry of disease a number of those extraordinary cases are recorded in which intelligent and conscientious persons voluntarily or involuntarily take the greatest pains to deceive their families, friends, and physicians, by the simulation of strange, diseased conditions. As a study, both in psychology and medicine, these chapters are most instructive. Indeed, the book throughout is so fascinating a one that it could not fail to be read entire by every one who begins its pages.

A Manual of the Practice of Medicine. By Henry C. Moir, M.D. 8vo., cloth. pp. 455. Published by the author, 211 East 31st street, New York. Price $2.50.

The author states his object in the preparation of the present work to have been "to present to the student of medicine and the general practitioner, who have not the time to read a large number of pages of an exhaustive treatise in order to obtain a single point which may appear to them of value, a work wherein the morbid anatomy, etiology, symptoms and treatment are arranged in such a manner that, in a few minutes, a disease can be reviewed. Further, this volume is of such a size that it can be carried, without inconvenience, in the breast-coat pocket, thus being especially valuable to the busy practitioner."

The third part contains tables of the symptoms of disease possessing a special diagnostic value and *their causes*, which the author believes are not to be found in the same classified and compact form in any book that has yet been published.

It further embodies the substance of a course given by a successful instructor to his students, in their preparation for competitive medical examinations.

At the end of the volume there are about four hundred prescriptions, arranged in alphabetical order, according to their therapeutical uses, which have been obtained from prominent members of the profession.

Such a work appears to us to have value for students. But we do not think that the general practitioner who has any proper knowledge of his profession will find it a very useful volume; though by its arrangement it may recall to his mind, here and there, features of disease which he may have overlooked or forgotten.

A Treatise on Bright's Disease and Diabetes, with Special Reference to Pathology and Therapeutics. By James Tyson, A.M., M.D., etc. Illustrated. Philadelphia: Lindsay & Blakiston. Cloth, 8vo., pp. 312. Price $3.50.

This volume is the outcome of some fifteen years' special study and observation in the class of diseases of which it treats, and it will be found to be a very well prepared monograph. The writer begins with a section on the structure of the kidney, gives the tests for albumen, discusses the source and mechanism of albuminuria, examines the various classifications which have been proposed for Bright's disease, and proceeds to describe its forms under the name of acute and chronic parenchymatous nephritis, lardaceous disease, interstitial nephritis and cyanotic in-

duration. A valuable chapter on retinitis in Bright's disease is contributed by Dr. William F. Norris, professor of ophthalmology in the University of Pennsylvania.

The last two sections, about eighty pages, are taken up with diabetes mellitus and insipidus.

The author gives a great deal of attention to the therapeutics of these diseases, and his words recommend themselves as sound and practical. His directions are clear and minute. The pages are well illustrated with wood-cuts and two colored lithographs representing the waxy casts and intraocular lipæmia.

On the Antagonism Between Medicines and Between Remedies and Diseases. By Roberts Bartholow, M.D., LL.D., etc. New York: D. Appleton & Co. 1 vol., 8vo, pp. 122, cloth. Price $1.25.

These are the Cartwright lectures for 1880, and the book is in fact a reprint from the New York *Medical Journal*, in which periodical they appeared a few months ago. Those who believe in the doctrine of Antagonism will find an ardent advocate of their views in this writer, and one who pushes his faith in it as far as they will desire. Not much attention is paid to those who object to the theory; they are set down as deceived by 'sources of fallacy" of various kinds. The extremely acute criticisms of the theory of antagonism, by Professor Gubler, are not satisfactorily answered to our mind. Nevertheless, there are many excellent observations and valuable suggestions presented which will repay the reader, even if he closes the volume convinced that the doctrine itself, regarded as a basis of therapeutics, is not merely a fallacious but actually a dangerous one.

Anatomical Plates Arranged as a Companion Volume for "The Essentials of Anatomy," and for all works upon Descriptive Anatomy, etc. By Ambrose L. Ranney, A.M., M.D. New York: G. P. Putnam's Sons, 1881. Cloth. Small 4to. Price $3.00. For sale by P. Blakiston.

This anatomical atlas is largely a reproduction of that of Prof. Masse, of Paris. It contains in all 124 plates engraved on stone, and generally clearly and accurately done. Opposite each plate is a page of text, giving a brief description of the section represented. Various diagrams are added by the American editor, to bring out more clearly the relations of the parts. Numbers are used instead of names, to designate the particular parts represented. The size of the atlas, being small quarto, is a decided point in its favor, and one that renders it at once more convenient to study and also much cheaper to purchase. The price at which the present atlas has been put is certainly very reasonable indeed, for the character and extent of the work.

How We Fed the Baby to Make Her Healthy and Happy; with health hints. By C. E. Page, M.D. 144 pages. Paper, 50 cents; cloth, 75 cents. New York: Fowler & Wells, 753 Broadway. For sale by J. B. Lippincott & Co.

The theory which this book is written to establish is, that "the chief cause of infant mortality is excessive feeding" (p. 28). It is often enough, says the author, for a baby to take the breast thrice in twenty-four hours. To feed it more frequently is to impair its digestion and to lead to imperfect nutrition with all its attendant dangers. The example of the author's own child is adduced as proof of the success of the method he recommends.

What Every Mother Should Know. By Edward Ellis, M.D., etc. Philadelphia: Presley Blakiston. 8vo, pp. 132, cloth, 75 cts.

Dr. Ellis is well known as a writer on diseases of children, his popular manual on that subject having gone through several editions both in England and America.

The suggestion was made to him that he should prepare a work in a popular form embodying the hygiene of infant life, and as much of the treatment of infantile diseases as the average intelligent mother may be supposed to comprehend. This he has done by expanding some of the chapters in his treatise, and throwing the material into a more popular form. His effort appears to us to have been a successful one, and all the usual points in such manuals are included. There are perhaps too many prescriptions given, some of by no means of inert character, the indiscriminate employment of which might be injurious.

The Diet Cure: An Essay on the Relation of Food and Drink to Health, Disease and Cure. By T. L. Nichols, M.D. New York: M. L. Holbrook & Co. Cloth, 8vo. pp. 88.

We can say little in favor of this book. It is the outcome of a hobbyism in dietetics, prepared by an English hydropathist, who adds his advertisement to his text. Though not an out-and-out vegetarian, he leans strongly that way, proclaiming that "fruit is the proper food for man." Disease he defines as "an effort of nature to cast out of the body some impurity, or poison." Again, "people who live as they ought, never need medicine." These phrases sufficiently stamp the general character of the work. It is not an exponent of science, but of prejudice.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

EXPLANATIONS OF MESMERIC PHENOMENA.

The revival of Mesmerism—to call it by its old name—in Germany, during the last year or two, has led to a swarm of articles and pamphlets on it of a more or less scientific character. What is wanted is a satisfactory explanation of the phenomena in accordance with the great advance of science since the days that MESMER so befogged the audiences of his day with his exhibitions.

It will be remembered that this famous charlatan first applied to the phenomenon in question the term of "Animal Magnetism," and explained it as "a mutual influence between the celestial bodies, the earth, and animated beings." His claims were considerably dashed in 1784, by the report of the committee appointed by the medical faculty of Paris, of which our own Benjamin Franklin was a distinguished member, which stated with definiteness that "there is no proof of an animal magnetic fluid; that having no existence, it is consequently without utility (!); and that the observed effects are due to the excitement of the imagination, and to that sort of mechanical imitation which leads us to repeat anything which produces an impression upon our senses."

The later committees appointed by the Paris Academy of Medicine in 1825 and 1837 were somewhat at variance, the former rather conceding the new force claimed, the latter stating that the experiments made were "certainly not in favor of the doctrine of animal magnetism."

It is unnecessary to refer to the writings of Mr. BRAID, who, about 1840, introduced the term "hypnotism," and offered a subjective explanation of the phenomena; and still less is it worth while to quote the vagaries of the clairvoyants and spiritualists, who so heartily embraced the magnetic theories.

Of late German explanations we may begin by bringing forward that of Dr. BERGER, of Breslau. He goes back directly to the report of the committee of 1784, as being nearer the truth in their explanation than any since offered. He attributes the main and decisive influence to the psychological factor of the attention and expectation being fixed upon a definite object or oc-

currence. The moment that the subject can withdraw his mind from the various manipulations, etc., and think of something wholly different, "the magnetizer" loses all his power. This is illustrated by the fact that in very young children, in the insane, and in those unconscious of the magnetizer's efforts, no such effects are produced. This writer does not deny that the effects are very decided in appropriate subjects; and he goes so far as to say, "The mental treatment of numerous cases of nervous disease has entered into a new career through the introduction of the hypnotic procedures; and they well deserve to be reduced to a method of therapeutics."

Another interpreter of the physiology of these phenomena is Dr. G. L. SCHNEIDER, of Leipzig. He has given especial study to the psychological processes. All voluntary action, he premises, rests on the gradual establishment of appropriate relations between an act of knowledge and an effort. These relations must exist before motion is produced. In the lower animals these relations are so inherited that as soon as a sensation is felt the effort and motion at once follow. So in hypnotized persons the consciousness is concentrated on one subject, and hence depressed in power. The motions are performed without full consciousness, and effort follows the impression without any clear knowledge of the relations between the two. This limitation of consciousness is brought about by fixing the mind for a considerable time on one impression, looking at a glass button, for example, or watching the magnetizer repeat monotonous motions.

Entirely reasonable action takes place only when the concentration of consciousness is manifold, that is, when it takes into account sensations, perceptions and ideas, and combines each in accordance with their respective values as instigators of motion; less reasonable action considers only one or the other of these, and allows it to control and direct effort. Persons in the hypnotic condition are thus governed by the one sensation on which their minds are fixed, and thus allow the other powers to lie dormant, their actions to be guided by the one predominant impression. Hence, all mesmeric appearances may, in psychological terms, be explained by one expression, and that is the abnormally limited concentration of the consciousness.

Such is SCHNEIDER'S theory; and it seems to be a satisfactory and philosophical explanation of the psychological phase of the phenomena.

QUESTIONS RELATING TO TYPHOID FEVER.

An eminent naturalist has asserted that in the development of the commonest weed all the great laws of biology are exemplified; not less true is it to say that the processes of any disease illustrate the pathological phenomena common to all. There is no necessity to wait for rare cases and extraordinary examples in order to pursue researches; maladies that are daily under observation offer a sufficiently great number of points for study.

Take one so prevalent as typhoid fever; how many questions of great interest concerning it are still unsolved! How does it arise? Is it contagious? Does the poison remain in the excreta mainly, or only? Has it a definite anatomical lesion? If it has, in what relation does this stand to the development of symptoms?

These are but a few of the inquiries which may be put about it, and how discrepant are the prevailing opinions about any one of them is obvious from the recent literature of the subject.

For example, on the presence and significance of the intestinal lesion we have the ablest observers at issue. The late Dr. Murchison, in his classical treatise on the "Continued Fevers of Great Britain," described "the specific lesions" of enteric fever, "which," he said, "*are invariably present*, and which consist in a disease of the agminated and solitary glands of the ileum." He added: "The morbid appearances presented by the agminated and solitary glands of the ileum are *constant in*, and peculiar to, enteric fever. '*Il faut*,' says LOUIS, '*non seulement la considérer comme propre à l'affection typhoïde, mais comme en formant la carac-*

tère anatomique, ainsi que les tubercules forment celui de la phthisie.' ''

When such eminent authorities as Dr. MURCHISON and Prof. LOUIS have thrown the weight of their opinions into the scale in favor of the view that the intestinal lesions of enteric fever are *invariably* present, one might hesitate to dispute the point. At the present day, however, it is almost universally conceded that enteric fever is an essential disease, its secondary intestinal lesions standing to it in the same relation as the rash and sore throat of scarlatina do to that disease. It would, therefore, seem only rational to conclude that cases of enteric fever may occasionally occur in which there is no disease of Peyer's patches and the solitary glands of the ileum.

Such cases have been reported, and basing their views on them, not less eminent authorities have denied any inevitable relation between the symptoms and the lesion. Thus Dr. STOKES, in his "Lectures on Fever," insists "that no form of fever has any special anatomical change, and that where such does take place it is of a secondary character. The lesions of the abdominal organs in fever are—not the cause—but the result of the essential disease." The same learned physician writes: "looking at fever in a wide sense, we may safely hold that these secondary anatomical changes are inconstant in their amount, in their nature, and even in their seat; inconstant as to their time of appearance, their symptoms, their intensity, and their decadence; and utterly incompetent to explain the phenomena of the disease."

To similar effect writes Prof. GUBLER, in his "Principles of Therapeutics."

Another question is the *contagiousness* of this fever. There is no doubt but that the drift of opinion has been, of late, in favor of the theory that it is positively and actively contagious. The matter has been actively discussed in the English medical journals during the last twelve months, and so many cases have been cited going to show this side of the case that it is impossible to deny their cogency. One of the medical officers of health, Dr. W. S. THOMSON, who has written considerably on the topic, maintains, moreover, that there is no proof that the semina of infection reside solely in the intestinal excreta. Typhoid fever, he claims, spreads by contagion, like other zymotic diseases, being transmitted into the body by inhalation into the lungs, by being swallowed with the drink or food, or by dust. The poison may not be so volatile as that of scarlet fever, and therefore requires a carrier or vehicle (currents of air are sufficient); and, when the patient is susceptible, it proves a highly contagious poison. The means to be employed to prevent its spread should be promptly and rigidly carried out. They consist of immediate isolation; thorough disinfection of excreta; procuring pure water; thorough disinfection of clothing by hot air at a temperature of 300°, or their destruction by fire; preventing children from going to school or other public resorts from an infected house without thorough disinfection, and not until it has been ascertained that the child is free from infection. There is risk in any susceptible person visiting the infected house. As rigid precautions should be employed as in cases of scarlet fever, substituting the disinfection of the discharges on their very issue from the body for the oiling of the skin, to prevent the spread of scarlet fever from the surface of the body. The practice of admitting typhoid fever patients into the wards of general hospitals is to be condemned. Nurses should be selected from those who are protected by a previous attack.

The vast practical importance of these views cannot be overlooked. The extension of a disease so common and so serious as typhoid is greatly to be deplored, and if it can be materially lessened by the adoption of such precautions, there should be no delay in making the fact known, not only to the profession, but to nurses and the public generally.

On the other hand, such an assertion as the above, as to the contagiousness of typhoid, is contrary to the generally received opinion, and would do great harm if, being an error, it were accepted as true. Hence, while such statements ought to be diligently canvassed by the profession, they should not receive hasty publicity.

Notes and Comments.

German vs. French Mineral Waters in Obesity.

The *Progrès Médical* observes that up to within a few years past the German Mineral Springs of Kissingen, Ems, and Marienbad had a world-wide reputation for the cure of polysarcia. As it were, they held a monopoly over obesity.

In 1874, Prof. Gubler, in a spirit of enlightened patriotism, spoke of the advantages which would accrue to the French Spas could a diversion in their favor be made among adipose patients—a numerous and wealthy class—whose patronage was then the exclusive privilege of the foreign watering stations. This wish has now been realized. Mr. Philbert, a sufferer from obesity, and who had followed the German reductive treatment, turned his attention to discovering, in France, a spring from which he and his fellow sufferers could obtain relief. He selected Brides, and has settled there.

His method of treating obesity rests on: 1st. Purgative effects; 2d. Sudation; 3d. Diet, and 4th. Physical exercise.

The evacuants he prefers are saline cathartics; hence the waters of Brides, which contain sulphates and chlorides of sodium and magnesia, could not be excelled. In doses of from three to four glasses on an empty stomach, in the morning, as many operations are obtained, without being attended by gripes or general debilitating effects. After two or three days diarrhœa sets in.

Sudation is brought on in a large and well-lighted vapor bath, which contains a spray douche. A sitting of forty minutes causes the patient to lose from 600 to 800 grams of his total weight, and this loss may be increased by means of frictions on the skin with a soap ointment.

At Marienbad great frugality is observed. But at Brides Mr. Philbert does not attach as much importance to the quantity as to the quality of food used by his patients. The diet consists in strict abstinence from everything that contains flour, starch, or sugar. Walking and fencing give exercise to the muscles. At first, the plethoric patient experiences great difficulty in taking long walks; but he soon becomes accustomed to this new mode of living, and by the time he leaves Brides the exercise has become a pleasure.

It is now some five or six years since Mr. Philbert has settled in this thermal station; he has had under his care a great many sufferers from polysarcia, and all have derived much benefit from his treatment. After a month's stay, the over corpulent lose, on an average, from twelve to thirty pounds in weight.

The only counter indications to which he calls attention are, either lesions of the heart, of the large vessels, or of the lungs.

Varices During Pregnancy.

The *Concours Médical* publishes an article on the above subject, from which we extract the following suggestions as to treatment: When varices appear as a complication of pregnancy all fatigue should be avoided, especially that resulting from prolonged standing. Women should carefully avoid all compression of the body that can interfere with free circulation of the blood. Œdema is to be opposed by keeping the limb in a horizontal position. This will also be found of service in inflammation of the veins. In case of hemorrhage the limb must be elevated still higher.

Compression is the most general mode of treatment. It is recommended by the majority of physicians, notwithstanding the fact that accidents, of rare occurrence it is true, have been attributed to this method.

For phlebitis, rest is of prime necessity. The limb should be kept in an elevated position, and poultices applied.

In cases of varices of the vulva or vagina, during pregnancy, it is prudent, as a *preventive treatment*, to discourage sexual intercourse, and recommend rest. At the time of delivery, if the veins exhibit too much turgescence, chloroform may be used so as to reduce the expulsive efforts. Notwithstanding these precautions, should hemorrhage set in, local digital compression is to be resorted to. This is tiresome, but it is the readiest method. Should it, however, fail, we must then have recourse to a tampon. But if labor is advanced, and the uterine orifice dilated, the best plan is to effect rapid delivery, and then resort to local compression.

Germs of Malignant Charbon.

In a recent note to the Academy of Sciences, of Paris (*Comptes Rendus*, No. 5, 1881), M. Pasteur states that there is a farm near Senlis, where many sheep annually perish of malignant charbon. These sheep have been interred in a walled garden; in one part none have been placed for twelve years. About two ounces of the surface earth was taken from this part; it was well washed and guinea pigs inoculated

with the smallest particles; the animals rapidly perished of malignant charbon.

Then at the farm seven sheep were each afternoon placed in this part of the garden; as there was no grass the sheep were fed at the stable, with the rest of the flock; notwithstanding this, two of the sheep soon perished of charbon, while the five others and the rest of the flock did not suffer.

Thus two sheep perished through the habit they have of turning over the earth, and yet no diseased animal had been interred in the spot for twelve years.

In this part of the garden were grown some of the vegetables used on the farm, and but one of the farm people suffered; he had been attacked by malignant pustule, which had not proven fatal.

These facts would seem to prove that vegetable combustion and assimilation do not destroy the germs of certain microscopic organisms which may be contained in manure or in the carcasses of dead animals.

Albuminate of Iron in Amenorrhœa.

M. Jugand reports the following case in *Le Progrès Méd.*, No. 12, 1881. Mme. L., aged thirty-five, presenting all the symptoms of chloro-anæmia, said that her health was generally good, appetite fair, her family antecedents were excellent. At the age of seventeen a few drops of blood appeared, but since that period there has been no menstrual flow. She was married when twenty-two years of age, and has each month the pains of uterine congestion in the back, in the abdomen over the ovaries, with a sensation of weight in the same parts.

Wishing very much to become pregnant, she consulted many physicians, and took every form of emmenagogue in connection with the local treatment, sitting baths, cold douches, injections, etc., all without result. Then for two years she took insoluble iron pills, inducing only digestive troubles. M. Jugand found nothing abnormal in his examination of the uterus, and advised the patient to suspend all treatment for one month, taking care to recommend a proper diet during this period. Shortly after, as there was some diarrhœa, albuminous water was prescribed, and at the same time syrup of the citrate of iron was given; it was well supported by the patient, and after six weeks a few drops of blood appeared. Noticing the coincidence, albuminate of iron (Lapradés preparation), was administered; during the four following months the menses appeared regularly, the fifth month they were wanting; the patient had become enceinte.

Aconite in Fevers.

The use of aconite in remittent fever is commended by Dr. G. Bomford, of Calcutta, in the *Practitioner*, March, 1881. He also speaks of it in typhoid fever, saying:—

I have often given aconite, sometimes for days together, to typhoid-fever patients, with a view to cleaning the tongue and inducing sleep. If pushed, it will reduce the temperature, but only temporarily. The fall of temperature, sometimes very remarkable, is not always accompanied by profuse sweating; and it cannot, I think, be explained, on the "heat loss" theory, as being the result of evaporation of the sweat merely. In many cases I have noticed a slight rise of temperature preceding the fall, which corresponds with Dr. Mackenzie's observations on rabbits.

There is no doubt that aconite acts most usefully when given in frequent small doses, but this cannot be explained by the supposition that it is rapidly eliminated, for marked toxic symptoms may occur many hours after the last dose. In all my cases, with one exception, the pulse has been improved in strength, as well as reduced in rapidity. The exception was a case of typhoid in a man who had suffered from a weak, irregular pulse for many years. The aconite seemed to increase this condition of the pulse, and was consequently stopped.

The Relation of Brain Structure to Intelligence.

There is plainly to be noticed a growing doubt among the most competent biologists as to there being any fixed relation between brain structure and mental function. That pet theory of a few years back is not now tenable. There is a *tertium quid* in the evolution and action of intelligence which we cannot yet put our finger on. An example in point may be mentioned, from a recent lecture of Prof. Calderwood, of Glasgow. Speaking of insects, he quoted Sir John Lubbock with reference to their position in the order of development. Sir John said that, though the anthropoid apes ranked next to man in bodily structure, ants claimed that place in the scale of intelligence. Once he had watched an ant working, and it worked from six in the morning to ten at night without intermission, carrying one hundred and eighty-seven larvæ to its nest. Professor Calderwood said that it be-

came apparent that anatomical structure was not in itself an adequate guide in determining comparative importance in the scale of organic existence, and that even comparative brain structure could not be taken as a sole test of the measure of intelligence. The whole order of ants presented quite exceptional difficulties for the theory of evolution, and also for the theory of intelligence, which seeks to account for it by complexity of brain structure.

The Treatment of Itch.

A writer from Paris says that at present itch is cured in one hour and a half, at the St. Louis Hospital. The first half-hour the patient, absolutely nude, rubs himself from head, or rather neck, to foot, with soft soap. The second half-hour he is put into a tepid bath, where he continues the soft-soap frictions. The third half-hour he rubs his body with Helmerich's sulpho-alkaline ointment. He puts on his clothes without washing off the ointment, so as to keep it in contact with the surface for twenty-four hours. While the patient is treating himself, his clothes are purified in a specially constructed stove, at a temperature of 120°, and exposed to sulphur vapor. Four thousand itch patients are treated here annually.

The hospital treatment is a rough one, and sometimes causes attacks of eczema. It may be mitigated thus: toilet soap is substituted for soft-soap, and Hardy's modification of Helmerich's ointment used, lard one hundred parts, sulphur sixteen parts, bicarbonate of potash eight parts, by weight. The patient should have his sheets and all under-linen changed immediately.

The Office of the Pacchionian Bodies.

The Pacchionian bodies, which are physiological structures, serve, according to Key and Retzius, to permit the passage of fluid from the cerebro-spinal serous cavities into those veins and sinuses of the dura mater around which they are grouped. If this view be correct, it is evident that they are specially likely places for the retention of any corpuscular contents of the cerebro-spinal fluid. Key's researches show, moreover, that these organs are much more widely distributed than has been supposed. Their great frequency at the base of the skull, and especially in the middle fossa, would lead, *à priori*, to the conclusion that this would be a favorable situation for the retention of tumor cells. As a proof of the truth of this view, Key relates in great detail, in a late number of the *Nord. Med. Ark.*, a case of fibro-cellular neuroma of the auditory nerve, with numerous metastases in the Pacchionian bodies on both sides of the superior longitudinal sinus, and also at the base of the skull, especially in the left middle fossa. The swollen glands had, in several places, caused loss of substance in the bone, similar to what frequently occurs in glioma of the retina.

Soothing Lotions and Potions.

The *Practitioner* states that Dr. A. Croz suggests that lotions may be made for application in those cases in which there is reason to fear the irritating or stimulating action of water; such lotions being made with a liquid does not present those inconveniences. To effect this object, he prepared fluids containing white of egg and sea-salt in such proportions as to approximate the composition of serum. For this purpose he gives the following formulæ, which he has found useful:—

1. Albuminous water.
   White of four eggs,
   Water, one quart
2. Eye lotion.
   White of one egg,
   Alum, ¾ grain
   Rose water, one ounce
3. Alum serum.
   Alum, two drachms
   Clarified serum, one pint.

A small glassful from time to time, to stop diarrhœa.

Experiments by Means of a Gastric Fistula.

A case like that of the famous St. Martin recently occurred in Spain, and has been experimented on by Dr. Rubio y Gale, as we learn from the London *Medical Record*. He took the opportunity to make certain physiological researches. As the result of these he found that, of all substances experimented with, albumen was that which passed most quickly from the stomach to the duodenum, while cod-liver oil passed the most slowly. The conduct of milk in the stomach differed essentially from the conduct of the same fluid with certain reagents in the atmosphere. In the stomach it did not curdle, but became a plastic, viscid mass, which followed the movements of the patient from side to side in a sluggish and imperfect manner. The secretion of the gastric juice was not constant, but took place at intervals; the contents of the stomach were also passed at intervals through the pylorus, which, in a state of rest, remained constantly closed.

Special Reports.

NO. X.—GONORRHŒA.

(*Concluded from page* 499.)

Abscesses.

Last year, Guiard, in the *Gazette des Hôpitaux*, No. 20, urged that phlegmonous abscess is much more common in gonorrhœa than is usually supposed. Méry's glands, Cowper's glands and the prostate gland are all liable to become involved. The acute inflammatory condition of Cowper's glands passes rapidly to the formation of abscesses, and must be treated by early incision. Generally, there is little constitutional disturbance. The diagnosis of this abscess depends on—

1. The inflammatory swelling is close to the bulbus urethræ.
2. It is limited to the location of Cowper's glands.
3. It has no connection with the urethra.

Gonorrhœal Ophthalmia.

In a paper read at the last annual meeting of the British Medical Association (*British Medical Journal*, November 13, 1880), Mr. Bader recommends the following plan of treatment, which he has employed with success, both in adults and children suffering from gonorrhœal ophthalmia, as well as in infants with purulent ophthalmia. An ointment containing one grain of red oxide of mercury, and one-fifth of a grain of sulphate of atropia to a drachm of vaseline having been prepared, the patient lies down, and if he be restless an anæsthetic may be given. The eye is first well cleansed with tepid water, and then the ointment is to be pushed freely beneath the upper and lower lids with a soft camel's hair brush, so as to cover the whole conjunctiva. The dressing is to be repeated daily at 9, 12, and 4 o'clock, until the eyelids open freely; afterward, once a day till the discharge ceases. The ointment is to be applied by the medical attendant himself. If the disease be recognized at the onset, only a few days' treatment will be necessary. The sound eye is to be kept bound up with lint, thickly smeared with the ointment.

In the *Recueil d'Ophthalmologie*, November, 1880, Dr. Mengin records a case of gonorrhœal iritis occurring in a rheumatic subject. The patient, aged 28, had a strumous history. He contracted gonorrhœa, and subsequently purulent ophthalmia, which destroyed the left eye; severe gonorrhœal rheumatism next followed, and this was succeeded, eight weeks after the first appearance of the rheumatic symptoms, by a typical iritis, which yielded to energetic treatment. The author, in such cases, insists on the importance of local depletion, and of strong solutions of atropine. In this case six leeches were applied round the orbit, and a ten per cent. solution of atropine instilled five times in the first half hour, and subsequently three times, the patient having been previously cautioned not to swallow his saliva during the instillations. A grain and a half of calomel was also administered daily during ten days.

Methods of Treatment.

Dr. W. Watson Cheyne's method of treating gonorrhœa by medicated antiseptic bougies attracted considerable attention last year, and though already pretty generally known, may here be described, as given in the *British Medical Journal*, July 24th, 1880. His bougies have the diameter of a No. 9 or 10 catheter. His formula is—

℞. Iodoformi, gr.v
Olei eucalypti, gtt.x. M.

In a bougie of grs. xl.

The specific element of the disease having been eliminated by this means, antiseptic injections are employed in addition, for the purpose of preventing the discharge from becoming septic and irritating. A saturated solution of boracic acid in water, or an emulsion of eucalyptus oil (one ounce of eucalyptus oil, one ounce of gum acacia, water to forty or twenty ounces), to be used for two or three days. At the end of that time injections of sulphate of zinc, two grains to the ounce, may be begun. The usual precaution of rest, diluent drinks, etc., must be employed.

In using the bougies, the patient is first told to empty his bladder, partly to clear out his urethra, partly to prevent the necessity of expelling the antiseptic from the canal for several hours. He then lies down on his back, and a bougie from four to six inches long is introduced, and the orifice of the urethra is closed by strapping. The bougie ought to be dipped in eucalyptus oil or in carbolic oil (one to twenty) before insertion. The patient is instructed to refrain from passing water, if possible, for the next four or five hours. If the case be severe and advanced, he takes another bougie home, and is instructed to introduce it in the same manner after he next passes urine. In the evening, or on the following day, he commences the antiseptic injection, which he uses four or five times daily. On the third or fourth day, when the symptoms have entirely subsided, an injection of sulphate of zinc, two grains to

the ounce, is begun. For a day or two the purulent discharge continues, but afterwards it steadily diminishes in amount, becoming in four or five days mucous, and ceasing altogether in a week or ten days. At the same time the scalding and pain and the symptoms of inflammation rapidly diminish, and disappear completely in about thirty-six to forty-eight hours.

Continuous irrigation of the urethra has been tried with good results, by Dr. Vajda, by means of a perforated catheter of soft rubber and a rubber water holder, described in *Schmidt's Jahrbücher*, Bd. 188, No. 11. He claims better results from this arrangement than from other means he has tried.

The *sulpho-carbolate of zinc* has been extolled by Dr. W. T. Parker, of Mass., as an injection in gonorrhœa:—

℞. Zinci carbolatis, ℥j
Mucilag. acac., ℥j
Extract opii aquosi, gr. j
Aquæ, ℥ vj. M.

Use as injection, night and morning.

Hydrastis still finds advocates. Bartholow recommends a drachm of hydrastia (the alkaloid) to four ounces of mucilage of acacia, and has found no injection so uniformly successful. Phillips prefers an injection made by adding one or two drachms of the tincture to a pint of water, and of this orders a syringeful to be injected up the urethra every half-hour for seven or eight hours, and then every six or eight hours for two or three days.

In the *Bull. Gen. de Thérapeutique*, 1880, Dr. Pasqua reports four cases of gonorrhœa in its early stage treated with a chloral solution:—

℞. Chlorali hydrati, gr. vj
Aquæ rosæ, f. ℥j. M.

Two urethral injections daily were used, the fluid being retained a few minutes in the urethra. Improvement began in four or five days, and the discharge ceased in eight or ten days. No unpleasant sequelæ appeared.

Dr. Herbert L. Snow publishes (*Brit. Med. Jour.*) the following formula, which, in his hands, has proved of great service, and which is not particularly unpalatable:—

℞. Ol. copaibæ,
Ol. cubebæ, āā ℥ij
Liquor. potassæ, ℥iiss
Tinct. aurantii, ℥iij
Syrupi, ℥ij
Aq. menth. pip., q.s. ad ℥viij. M.

Sig.—Two tablespoonfuls three times daily.

Granular Urethra.

Dr. Eldridge, of Yokohama, after an operation for stricture of the bulbous urethra, found, by means of the endoscope, a granular condition of the urethral mucous membrane for about two inches. A gleety discharge was also present. Ergotine (Bonjean's) was applied by means of an ointment syringe, and the patient kept recumbent for an hour afterwards. After six applications on alternate days the gleet had entirely disappeared, and there was no trace of granulations to be discovered.

Orchitis Treated by Topical Applications of Iodoform.

Dr. Sabadini lately communicated to the Medical Society of Constantinople the details of a case of blennorrhagic orchitis successfully treated by him with applications of iodoform.

The patient, a waiter in a hotel, could not give up his occupation for the purpose of undergoing treatment, without fear of losing his place. The swelling of the testicle was very great. Dr. S. determined to treat it by the aid of iodoform, according to the method reported in the *Archives Med. Belges*, and recommended by Dr. Bourdeaux, who asserts that by this treatment all acute pains disappear, and the patient is not prevented from attending to his business. Dr. Sabadini therefore prescribed an ointment of four grains of iodoform to forty grains of vaseline, as an application on the tumor. The effects were surprising; pain soon disappeared, the patient was not obliged to give up his situation, although it kept him on his feet all day, and in the space of a week every trace of swelling had disappeared.

Soft Rubber Tubes for Injection.

Dr. W. T. Parker (Boston *Med. and Surg. Journal*, February), calls attention to the unsatisfactory urethral syringes generally manufactured. He observes:—

The syringes found in the drug stores are usually made of glass or rubber, with very small, pointed nozzles; they are apt to irritate the urethra, and are also objectionable for the following reasons: (1.) It is quite impossible to introduce the nozzle painlessly. (2.) It is difficult to compress the penis tightly about the nozzle without pain. (3.) The injection pours out at either side of the nozzle after introduction, without entering the urethra far enough to be of any value. (4.) The constant use of the hard rubber or glass nozzle is apt to create an ulcerated spot where the point touches the lining of the urethra.

It is evidently important to avoid all these accidents, to treat a case successfully. The cure of many cases is delayed, and the chances for stricture increased, because a good syringe cannot be found. At least, I am sure that such has been the experience in my own practice.

To remove some of the difficulties encountered at present in the treatment of urethral inflammation, and to facilitate the injection of the urethra without pain, Messrs. George Tiemann and Com-

pany, of New York, have made for me some "soft rubber. velvet-eyed tubes, with bulbs, for making the injection painless."

They are about two and a half inches long, of three sizes, the bulbs corresponding with Nos. 13, 15, and 17. Tiemann and Company's American scale. They are made of pure rubber, soft and pliable. The movement to the right or left of the syringe in pressing out the fluid cannot cause pain, because only the rubber tube *beyond* the attachment to the syringe is to be introduced; they are easily introduced painlessly, and compressing the penis about them to retain the injection is also painless. The bulbs have very thin walls. I find these tubes excellent in practice, and very highly appreciated by those who have been tormented with ordinary syringes. They fit easily on the nozzle of almost any syringe. The hard rubber ear syringe, with the ring for self-injecting, I find preferable to all others.

Correspondence.

Epidemic Metastatic Paro iditis.

Ed. Med. and Surg. Reporter:—

In a communication from Dr. Skelley, in the *Medical Record*, of New York, for February 26th ult., the subject of Orchitis following Parotiditis, in relation to its frequency and gravity, is discussed, giving several cases where it resulted neither from exposure to cold nor was anything like the "bugbear" we are generally taught to regard it. As the subject is but little dwelt upon by most of our works on surgery, if at all—several absolutely ignoring the subject, and some regarding it of so rare an occurrence as not likely to come under the treatment of the ordinary physician—a few statements by one who has just passed through an epidemic of this affection may be of interest.

It found its way into our community some time during the month of November last, occurring in an isolated case about eight or ten miles from town, in the person of a young man seventeen or eighteen years of age, hired upon a farm as an ordinary farm laborer. At first the case presented the ordinary features of parotiditis simplex—the right side being affected—with all the symptoms peculiar to the disease. Before the right side had quite run its course, however, the left commenced to swell, and before this had quite subsided, the right testicle, and afterwards the left.

So long as the affection confined itself to the parotids the young man felt no alarm, and merely resorted to the treatment in domestic use. When it seized the testicle, however, it was attributed to cold, and immediately communicated great alarm. As this took place one unusually stormy night, about midnight, my presence was immediately summoned to the bedside by a messenger who came in the greatest haste, breathless and bathed in perspiration. Beyond the scare the patient received, the case was doing well enough at the time, and I could no nothing more than assure him that he would be all right again in the course of a week or two, and advise him to keep the painful testicle suspended in a bag made for the purpose, containing a warm, soft, bread-and-milk poultice, with the addition of a teaspoonful of laudanum. These poultices were ordered to be continued so long as the swelling remained, and beyond some bismuth powders, for the vomiting consequent upon the transmission of the affection and the painful condition of the testicle, nothing further was done.

The young man having a great many friends in the neighborhood, was the recipient of a great many calls, consolatory upon his peculiar confinement, and it was in this way that the disease spread. In less than a month not only the young man's friends were afflicted in the precise manner, but nearly the whole neighborhood, young and old, male and female; the females suffering from no metastasis, however, to my knowledge. Some families had as many as four or five confined at one time, all the males afflicted in the same manner. In the course of the four months ensuing it had worked its way into town, and is now among us at the present writing.

If this is not *epidemic and contagious*, what is it? Far from being rare, as both Erichsen and Flint would have us believe, it seems to be uncommonly common, notably so with us. Dunglison and Hartshorne, of all the writers on the subject, regard it as epidemic and contagious, and the above facts, faithfully and truthfully given, should more than confirm them in their statements.

Assuming, as it undoubtedly does, a form both epidemic and contagious, would it not be well to give it a distinct classification as a disease, and call it metastatic parotiditis? robbing it of its terrors as well.

The epidemic now among us, it may be necessary to state, has been so far an extremely mild one, no deaths having occurred from the disease, either directly or indirectly, although the winter has been an unusually severe one. One instance only has come to my knowledge, where the testicles were not attacked, and that occurred in my own practice, in the person of a brakeman, a young man, nineteen or twenty years of age, whose parents reside here, and who was taken with the epidemic while on a visit to them several weeks ago. An instance also occurred where the ovaries seemed affected, very likely from metastasis, in a young girl, fourteen or fifteen years of age, and in which pressure in their region developed extreme tenderness and pain as well as vomiting. The vomiting, in fact, was a prominent symptom throughout the entire course of the disease. In a great many instances, however, this was also the case in those in whom it attacked the testicles.

Peabody, Kansas. Chas. H. Miller, M.D.

Fecal Fistula, from Gunshot Wound.

Ed. Med. and Surg. Reporter:—

The following case of gunshot wound followed by a fecal fistula of seven weeks' duration, and recovery, occurred in my practice, and may possibly be of sufficient interest to justify publication.

Aug. 15th, 1878, 5 o'clock P.M., I was called to attend John Anderson, a Swede, age 45 years, a raw-boned giant, of superlative vitality. Found him with a gunshot wound in abdomen, one inch below a line drawn from to the right of the umbilicus and three inches from the median line. The ball (a half ounce) had entered in front and passed backward and upward, striking and fracturing the crest of the ilium, lodging under the skin in the back. I saw him in five minutes after the wound was received. I at once ordered him to bed, and after giving him a large dose of brandy, cut the ball out. He was then placed upon his back and morphia, in quarter-grain doses, was given every two hours, with drop doses of aconite. I feared the ascending colon had been wounded, and, of course, thought to find him dead next morning, or that fatal peritonitis had set in. I now give my notes of the case.

Aug. 16th. Deeply narcotized. Bowels quiet. No pain. Pulse 100, temperature 101°. Ordered treatment continued, and no solid food to be given, only milk and strained soup. Evening call found about the same state of affairs.

Aug. 17th. Temperature 102°, pulse 90. Still under the influence of the opium, but continued it. Bowels unmoved. This state continued with but little variation for fourteen days, when, to satisfy the clamor of his friends, more than anything else, I gave him an enema and relieved the lower bowel. This was done at the morning visit. Upon calling in the evening I found fecal matter discharging from the posterior wound, and was confirmed in my diagnosis. It also proved to me that my efforts were rewarded by adhesion of the bowel to the wound of the posterior internal wall of the abdomen; as, if such had not been the case, the matter would have been forced into the peritoneal cavity by peristaltic action, instead of through the narrow opening outward. The anterior orifice had by this time healed entirely. I continued the treatment seven days longer, and relieved the bowels again with an enema. The next day after I had discontinued the morphia a most unexpected complication occurred, whether from the position so long sustained, or from the narcosis produced, a most violent cough, with profuse expectoration of pus, more in resemblance to the sputa of chronic bronchitis than of pneumonia. Comp. syr. of tar was given and the case treated as symptoms arose. The cough lasted but a short time, and at the end of the seventh week he was able to go to his home, three miles from town. No after trouble occurred, except a discharge of the pieces of bone shattered from the ilium, that continued for several months, when it ceased, and the posterior wound healed.

Summing up the case, I will say that wounds of the bowels are seldom recovered from. Rest was the whole aim of the treatment; the position the patient was placed in was for the purpose of bringing the wounded part of the gut in contact with the wounded wall of the abdomen, and hoping adhesion would take place after the peristaltic action of the bowel had been paralyzed by the opium. The aconite was given to subdue any undue inflammation, and the purpose of the liquid diet every one understands.

Three years after the occurrence of the accident he is a strong, healthy man, able to do the day's work of a farmer, suffering no inconvenience except a "pulling at the small of the back when he makes an extra effort in lifting." No pulmonary trouble has occurred since.

Elizabethtown, Ky. A. W. Morris, M.D.

Treatment of Pneumonia.

Ed. Med. and Surg. Reporter:—

I wish to add my thanks to those already expressed to Dr. Corson for his defence of correct treatment of pneumonia, and express my wonder that the stimulators have so long gone unrebuked. I have been in the practice thirty-seven years; half of that time have been what we call busy; have never lost a case of pneumonia, although I suppose I have had the usual proportion of that disease in my practice. If I get them before disorganization has taken place, especially if I get them during engorgement or congestion, I take pneumonia with as little concern as I do chicken-pox or mild measles. Well, they (the stimulators) may ask how I treat it. I answer, pretty much as Watson directs, and if I must be bound by book directions, I would take Eberle rather than our modern authors. When called to a case, if the patient is able to sit up I have them do so; generally have the feet put in water as hot as they can bear, and let it be the business of some one to keep it so while I bleed from a large orifice until they breathe easier or become faint; generally, both occur about the same time; then have them lie down, rub the feet and wrap them up warm; give a full Dover's powder. They will take a sleep, wake up better, and often need no more medical treatment. If they do I continue the pulv. Doveri, with as much tart. emetic as the stomach will bear. I seldom bleed more than once, but often follow the bleeding by cupping. Mercury is often necessary, especially if the pleura is involved, and many cases do not do well without a blister, when early treatment has been neglected. Dr. Corson speaks of the strange fact that so many of our prominent men die of pneumonia. This reminds me that one of the members of our last Constitutional Convention was arrested by pneumonia on his way home, was treated by the stimulators, and—as I expected—died. I say as I expected, for I expect all to die who are thus treated. Since that, the doctor who had control of the case died (I learn) of pneumonia. As for veratrum and aconite, they are about as good a substitute for the lancet in the hands of the physician as a harrow is for a plow in the hands of the farmer. To discuss the pathology of pneumonia here, or the philosophy of the operation of remedies, would be folly. Every one knows that the blood, if it accumulates in the lungs to a sufficient extent, will kill, either immediately by congestion, or subsequently by inflammation. I am satisfied that I have seen cases threatened with death by congestion entirely relieved by one full bleeding, with *heat to the extremities*. Many reasons there are for this opposition to bleeding; some, I suppose, are believing it wrong. I know some who, I believe, quit bleeding because they could not

keep an instrument fit to bleed with, or perform the operation in a decent manner with a good instrument. Some are too lazy. B.

Cardville, Pa.

A Case of Triplets.

Ed. Med. and Surg. Reporter:—

Was called at 3 A.M., on the ninth inst., to see Mrs. L. R. Her husband told me she was in the seventh month of pregnancy, but had been having some pains and something had passed from her.

Living close by I was soon there, and upon examination found a protrusion of the bag of waters larger than a man's fist, and lying in the protruded bag was the arm of a child. I at once ruptured the sack, found the head descending, and delivered her speedily of the child.

Upon introducing my finger into the vagina I found another head presenting, and soon delivered the mother of a second child. I then placed my hand upon the abdomen, to see if the womb had contracted and to use Crede's method of delivering the placenta, when I found the fundus still high up in the abdomen, and upon introducing my finger again into the vagina I found the foot of a third child presenting itself, which was delivered without any difficulty.

The children were all born alive, but one died about twenty-four hours after delivery, and the second one about forty-eight hours after.

Two were boys and one a girl. They weighed about four and a half pounds each.

The woman's size did not lead her to suspect more than one child, nor did she think she had gone to full term.

She had had six children previously, and never more than one at a time.

There were two placentas united by a membrane, one of which had two cords attached. I ruptured the membranes containing the first and second child. The third child was either in the same bag as the second, or the membrane ruptured of itself.

I believe the ratio of triplets is about one to five thousand births. This is the first case that ever happened in this county.

J. F. Force, M.D.

Heron Lake, Minn., April 13th, 1881.

News and Miscellany.

Medical Practice in Southern Africa.

In a recent communication to the Vienna Medical College, Dr. Emil Holub observes that the number of foreign physicians in Southern Africa, which some fifteen years ago was very small, has of late greatly increased; within the last year eighteen doctors, mostly Germans, have settled in that country, which offers a very remunerative field. His advice to the merchants settled there is to encourage their sons in the study of medicine. Both the natives, and the colonists among them, chiefly the Dutch, hold doctors in high esteem, the natives, because they believe them possessed of witchcraft, and the colonists, because they take fright at the least ailment. This influences the rates of fees, and in Capetown half a crown (sixty-two cents), is paid for a call, while in Fort Elizabeth the price is five shillings and in the Transvaal six; for a consultation a pound sterling is charged.

There are doctors who, in a short time, have laid by fortunes of from 30,000 to 40,000 florins. In his practice among the negroes, a physician is obliged to observe great prudence, their lack of confidence and superstition continually throwing obstacles in his way. The Betshuans, for example, believe that every case of death is caused by poison; others refuse all medicines which do not produce instant relief. The native doctors are known by different names among the tribes, and their personal influence is very great, even with the King. Their prescriptions are composed of a few medicinal plants, and they work upon the superstition of their patients by a number of magical practices.

Dr. Holub's observations are interesting, chiefly as regards tuberculosis. He has never met with this disease on the table lands of South Africa; and, from experience with a great number of patients, he has found the curative virtues of that climate greatly superior to those of Madeira. He then describes the negro doctors, sorcerers, and nyagas, whose only art consists in knowing the virtues of certain plants. Not long ago, all those magicians were slaughtered, and their chief, King Seppopo, had to run away.

In Reference to Trichinosis.

It is interesting to note the quite different opinions on the prevalence of trichinæ, some saying the danger is next to nothing (how do they know it?), and others that it is more grave than we yet imagine. We are ourselves inclined to agree with the editor of *Science*, who says, in a late issue:—

"We have one word of advice to those who would preserve the United States export trade in pork, and that is to admit the existence of Swine Plague, and the increasing contamination of pork by trichinæ. This done, it is not difficult to organize such a system of inspection as will satisfy foreign governments that the shipments of pork from this country are such as can be received with safety."

Meanwhile we note that Messrs. Lennis and Duncker, both of Berlin, have published an interesting paper in the *Zeitschrift für Mikroskopische Fleischschau*, on a new parasite with which they have met while performing their official duty. In examining pork for trichinæ they discovered a vermicular *diatomea*, imbedded between the muscular fibres, which they describe in the following terms: It is exceedingly thin and transparent, of a grayish color, and of about the size of the cyst-wall of a trichina.

Professor Leuckardt is inclined to consider its presence in the pork as accidental, and believes that it is of little importance to government inspectors of meat in their official work.

Two cases of death occurred in Philadelphia, April 5th and 6th, from trichinosis. After eating from a boiled ham, four persons in a family were taken severely ill, and the two youngest died in four or five days.

The Regulation of the Sale of Patent Medicines.

The effort is making, in various quarters, to limit the sale of patent and proprietary medicines. A bill to this effect was proposed at the past session of the New York Legislature, but apparently did not pass. As a matter of general interest we mention its provisions.

It was in five sections. The first provided that all patent and proprietary medicines should have their exact composition printed upon the exterior of the bottle, box, or package in which they were sold; the second, that three commissioners, the chairman of whom should be the president of the county medical society, should have the power of examining all such medicines, and, if necessary, the process of their manufacture, when, if they found nothing injurious in their ingredients, they should be required to furnish a certificate to that effect; the third provided that such commissioners should receive pay at the rate of ten dollars a day for all time actually spent in the performance of their duties; the fourth provided that certain penalties should be inflicted for infringement of the law; and the fifth, that the act should go into effect immediately.

While some of these provisions are well enough, they are by no means all free from objection.

A Reverend Physiologist Abroad.

The Rev. Joseph Cook has been demonstrating physiology to the Scots. How he does it and what is thought about it may be judged from the following extract from the London *Medical Press and Circular*:—

There is no class of men who are more alive to the evil effects of intemperance than medical men; at the same time, and from that conviction, they must deplore such *ad captandum vulgus* arguments as those advanced by the Rev. Joseph Cook in his Free Assembly Hall lecture in Edinburgh. The lecturer, we are informed, proceeded to illustrate, by pouring alcohol on the white of an egg, the effect of drinking upon the albumen in the system! and he futher stated that by hardening the albuminous substances in the body *alcohol left scars on the brain and nerves which could not wash or grow out any more than scars in the skin.* In a professional journal it would be insulting to the sense of our readers to point out the groundlessness and fallaciousness of such statements and experiments.

Sanitary Insurance.

There has been organized in London a society with the novel purpose of protecting the occupants of houses against unhealthful surroundings. It is called the "Sanitary Assurance Association," the English using the word "Assurance" in the sense of our "insurance" (of the two, ours is the more correct, "assurance" being, in fact, in this sense, a French word). This Society provides for the inspection of any building desired, by skilled officials; and these latter will, when required, draw up a report of whatever place they may be directed to examine, describing its actual sanitary condition, the alterations necessary to make it sanitarily perfect, and an estimate of the probable cost such alterations should involve. That such advice as a report of this kind would convey is imperatively called for in respect to the vast majority of houses is only too evident from the large number of deaths and diseases traceable to defects in sanitary construction.

Mushroom Poisoning.

A letter to *Science* says:—

A very peculiar case of poisoning occurred a short time ago at Puy l' Evêque, an account of which was sent to the Académie de Médecine by Dr. Demeaux. It seems that a family composed of five persons was taken violently ill after having eaten some mushrooms. One of the mushrooms left from dinner was sent by Dr. Demeaux to the Académie as a specimen, and upon being examined by M. Chatin, was found to belong to one of the numerous varieties of the *oronge ciguè* species, called the *Amanita bulboza.* Nine-tenths of the mushroom poisoning we hear about is due to this *Amanita*, which, on account of its white color, is frequently mistaken by the inexperienced and unsuspecting for the harmless mushroom. It is certainly the height of folly for people to run about the woods and fields mushroom hunting, unless they are perfectly familiar with the different species.

Sisters of Charity as Nurses.

The plan has been actively pushed in Paris to dispense with the services of the Sisters of Charity in the hospitals, and substitute paid nurses. About one-third of the medical officers of the hospitals are opposed to the change, and have protested against it. The Municipal Council is for the change by a heavy majority, and are about to open a "municipal school for nurses" at the La Pitié Hospital. One objection urged against the sisters, is their proselytizing tendencies. From our own observations in the class which fill the Paris hospital, such, or any kind of religious admonition would not be amiss.

Causes of Deaths in Great Britain.

Prof. de Chaumont, of London, states, that of the 700,000 deaths per annum in Great Britain recorded by the Registrar-General, consumption caused about 70,000; diseases of the respiratory organs, 100,000; diarrhœa, 33,000; enteric fever, 11,000; scarlet fever, 25,000: and diphtheria, 3500. Some of these diseases might be prevented altogether if dwelling-houses were put in a good sanitary state, and others might be modified to a very material extent, the whole of them being propagated by foul air and foul water.

—*John Thomas*—"Did you ring, sir?" *Surgeon* (just arrived at country house)—"Yes. Why have you laid out my surgical instruments on the dressing table?" *John Thomas*—"Surgical instruments, sir? I thought them things was what you dressed for dinner with?"—*Punch.*

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

INDIGESTION DUE TO NERVOUS INFLUENCES.

BY CHARLES R. CRANDALL, M.D.,
Of Philadelphia.

It has long been noted that certain forms of indigestion were dependent upon, or associated with, morbid states of the nervous system. If it was possible to outline such cases in all instances, and say accurately where purely nervous influences began and ended, much would be accomplished toward simplifying a most obscure class of affections. As it is, however, more or less inference, and many facts regarding the development and continuance of a morbid state of the digestion, must be drawn from such habits of life and such symptoms as are associated with expressions of marked nervous phenomena.

That hereditary influences of a nervous character, antagonistic to healthy digestion, exist, there can be no doubt. Children born of nervous and dyspeptic parents are undoubtedly more or less congenitally liable to attacks of indigestion, which are of a purely nervous origin. Such children, during infancy, are especially prone to attacks of vomiting and diarrhœa, from slight improprieties in diet, from the effects of teething, and from changes in the weather. Upon reaching childhood this class are usually excitable, emotional, poorly nourished, and suffer from indigestion whenever depressed from exposure, from overplay or juvenile dissipation. At time of puberty and subsequently, children thus nervously endowed invariably suffer from habitual indigestion, mal-nutrition, chorea, headache, neuralgia, and are easily depressed by excesses of any kind which tend to exalt or exhaust the nervous system. They seem wanting in nervous stamina, in vitality and endurance, and whenever deranged from any cause which makes a powerful impression upon the nervous system, show such evidences of disordered digestion as sick headache, vomiting, loss of appetite, constipation or diarrhœa. Their natural weakness appears to be in the organs of digestion.

As a second cause, tending to originate indigestion by means of impression upon the nervous system, may be mentioned weather and the climatic changes. The marked effects of changes in the weather upon infants is well known. Very frequently they perish in a few days, from deranged digestion induced primarily by a change in the weather from a cool temperature to a hot, murky state.

Adults, not organically diseased, but of moderate or impaired vitality, emigrating from a cool to a warm, prostrating climate, often suffer great nervous depression from prolonged heat. Their symptoms will point chiefly to impaired nutrition, and they generally complain of debility, "biliousness," loss of appetite, constipation, or diarrhœa. Indeed, this class of persons, having been stimulated and held up by the cool air of their native heath, invariably fail, and often die, when exposed for a time to the depressing effects of extreme thermometric and barometric changes. Their general condition not being healthy and vigorous, they are unable to withstand the increased waste of moisture, fat and musculine, which is so strikingly shown in many persons by a failure of bodily weight, muscular strength and nervous energy.

Perhaps, the most powerful nervous influence which tends to cause poor digestion is predisposed by sex. High authorities estimate that females are ten times more liable to nervous disorders than males. By nature, they are less rugged, more emotional, and more highly organized, and hence are more easily influenced by whatever affects the nervous system. Furthermore, they are naturally and frequently liable to peculiar disturbances resulting from the function of generation, which also renders them additionally susceptible to extraneous influences. As an outgrowth of such natural state, it is a very common thing to find among this class disorders which are purely nervous in character. There will frequently be evidence of hysteria, anæmia, mental excitement, some form of uterine or ovarian disorder, and then, superadded to all, marked derangement of the functions of digestion. When symptoms of indigestion do exist, they are usually pain in the stomach and bowels, vomiting, flatulence, and habitual constipation, all of which are more or less characteristic of nervous phenomena.

Another origin of disturbed digestion is the powerful influence of intense mental operations. It is a fact, that is known alike to the laity and the profession, that in many instances digestion is largely dependent upon the state of the mind. With very many persons, whatever tends to make a profound mental impression, other than of an agreeable nature, tends also to either retard, excite, or suspend digestion. Grief, excessive care, constant anxiety, business misfortunes and surprises, not infrequently destroy appetite at once and cause attacks of acute indigestion, sick headache or diarrhœa. These attacks are usually characterized by prostration, dry mouth, coated tongue, nausea, vomiting and a loathing of food. In such instances the nervous system has been shocked and depressed, and, as a resu't, there is almost a complete suspension of the functions of organic life. Of the immediate exciting causes, sudden emotions, especially of a depressing kind, are among those most frequently cited as having given rise to these disorders; but a similar effect may be produced by moral affections of the same character acting through a longer period. The influence exerted by painful emotion, not only in arresting digestion, but in producing painful sensations in the epigastrium, is well known, and the effects are greatly heightened in case of patients whose nervous susceptibility is more than usually prominent (Fox). An arrest of intestinal digestion may take place from causes other than errors of diet, and give rise to diarrhœa. A strong mental emotion may have this effect. I was present at an operation for hernia when the surgeon, from the mental anxiety incident to his sense of responsibility, was obliged to relinquish the scalpel and precipitately retire to evacuate the bowels. A gentleman in business receiving, suddenly, unexpected information which led him to know that he was bankrupt, was immediately seized with diarrhœa (Flint). Thus, it will be seen how powerful mental impressions, acting through the sympathetic system, may, in some form, completely "upset" digestion; and it is only reasonable to suppose that continuous mental excitement or depression would sooner or later establish a chronic morbid condition.

As a cause of great importance, giving rise to marked manifestations of nervous influence upon the organs of digestion, is hysteria. In this disease, which is supposed to be due largely to exhaustion and mal-nutrition of the nervous centres, there is a tendency to more or less pain, which is almost invariably referred to the stomach and intestines. Out of three hundred and fifty-eight cases analyzed by Briquet, one hundred and eighty-seven had both pain and derangement of the digestive functions. The nervous manifestations in this peculiar disease are many and well known. Among the symptoms, however, usually referred to the organs of digestion are pain, vomiting, flatulence, acidity and spasm. Indeed, the phenomena may extend to the bowels, giving rise to intestinal indigestion, constipation, abdominal rigidity and phantom tumors. Hence, in a great percentage of all the cases of hysteria there are marked and characteristic nervous influences which tend to produce disturbances of the process of diges ion. Most hysterical patients are out of health, many of them being weak and anæmic. It is a remarkable fact, however, that even when they eat a very small amount, nutrition often does not seem to fail. Among the numerous symptoms complained of in different cases may be mentioned *digestive disturbances*, especially flatulence, copious eructations, cardialgia, depraved appetite, fullness after food, obstinate constipation, intestinal colic or gastralgia (Roberts).

Nervous disorders referable to the function of digestion frequently result from an immoderate use of tea, coffee, tobacco and alcohol. In moderate quantities, tea, as a rule, is a very grateful beverage to most people, and is well borne by the system. When used in excess, however, and especially by persons of susceptible temperament, it causes marked derangements of the nervous system. It gives rise to a peculiar exalted nervous condition, generally termed "nervousness,"

which is characterized by pallor, wakefulness, impaired appetite and constipation.

Coffee, while, as a rule, one of the healthiest of beverages, nutritious and well tolerated, may, when taken in excessive amounts, especially by those whose digestion is not in healthy activity, produce distressing evidences of indigestion. Under such circumstances, it will cause marked nervous manifestations with which will be associated characteristic symptoms of indigestion. Hence, it is not uncommon to meet coffee drinkers who suffer from trembling of the hands and limbs, headache, giddiness, irritable heart, pain in the stomach, acidity, flatulence, "biliousness," "belching" and constipation. Simple loss of functional power is also produced by causes immediately affecting the stomach, such as excess of fluids taken at meals, especially when drank warm, or by abuse of narcotics, and of tea and coffee (Fox).

The action of tobacco upon the system is several fold and powerful. That it frequently tends to impair digestion all authorities bear uniform testimony. It may influence digestion by acting as an irritant to the mucous membrane, or it may act as a depressant upon the nerve centres. While well tolerated by the majority of those who become habituated to it, there are, nevertheless, many who are injured by even the most moderate indulgence. Among the latter class it tends to lessen the appetite. waste the saliva, coat the tongue, and so irritate the mucous membrane of the stomach and intestines as to cause chronic indigestion. With these symptoms are also associated its well known action upon the nervous system in causing trembling of the limbs, a weak heart, giddiness, and confusion of mind.

Most authorities agree that alcohol, in a very limited amount, favors digestion. It stimulates the gastric glands, causing them to secrete a greater quantity of gastric juice. But when used habitually to any extent, it tends to produce hypersecretion; it tends to dilute the gastric juice and it also tends to precipitate the pepsin. The secretions thus modified are to a certain extent destroyed for healthy digestion, and, as a result, an abnormal condition is established. In just what manner alcohol acts upon the stomach is probably not well known, but it is reasonable to believe that it stimulates the nerves distributed to the gastric glands, mucous follicles and muscular layer. In accordance with the well established law, that over stimulation is followed by depression, in time nervous energy is much impaired and consequently digestion suffers. Moreover, when taken in large quantities it tends to depress the nerve centres and suspend the action of the brain, which, in turn, is followed by a loss or suspension of nerve and muscular power. With nerve and muscular power thus suspended, the action of the stomach, being dependent upon both, is disabled, and digestion necessarily fails. When such a state of affairs is once established there will also be witnessed the familiar nervous symptoms common to excessive use of alcohol, namely. capricious appetite, uneasiness and pain after meals, morning vomiting, internal heat, craving for drinks and constipation.

Nervous exhaustion is another cause of marked and persistent disturbance of digestion. In the common strife for wealth, fame, fashion and intellectual excellence, together with the tendency to indulge in excess, thousands of persons exhaust their nervous energy. In addition to the wear and tear incident to such a strife, there is also a tendency to goad the nervous system with stimulants, and burden the mind with the depressing influence of fear and anxiety that the object of immense effort will not be attained.

Thus, in a manner both common and disastrous, nervous energy is exhausted and the power necessary to carry on the functions of organic life is largely consumed.

The deleterious effects of such profound and lasting nervous influences upon the functions of digestion cannot be over estimated. Hence, indigestion is one of the most marked symptoms of the morbid condition now recognized as neurasthenia. From want of nerve force, the organs of digestion are no longer able to act, and, therefore, there arise successively all the characteristic evidences of general torpidity of the alimentary tract. The stomach being debilitated, digestion will be slow, causing gastric catarrh and the usual associated conditions of fermentative changes, acidity, flatulence, and pain. The intestines being also wanting in nervous and muscular power, there will be neither healthy secretions, absorption or peristaltic action, and, consequently, the most persistent and obstinate constipation will exist. Of the special determining causes, *exhaustion* plays the most prominent part, and when combined with other depressing influences, and particularly those of a moral character and operating through the nervous system, such as grief, fear, anxiety, or severe intellectual effort, it is an almost unfailing source of perversion of the functions of the stomach, which can only be referred to disturbed innervation. These, however, may originate under almost any circumstances of in-

paired vitality or of diminished constitutional power (Fox).

In addition to the above-mentioned causes which tend to produce indigestion by impairment of the nervous system, it will be proper to allude briefly to three internal, or centric, morbid conditions, which have a similar effect. These to be referred to are common and highly important to be borne in mind when inquiry is being made into the causation of indigestion.

Accepting the modern view of eminent gynæcologists, that chlorosis, "the green sickness," is "probably a neurosis of the ganglionic system of nerves," a cause is recognized for a marked disturbance of digestion, the origin of which is in the nerve centres. In many instances it is difficult to differentiate chlorosis from anæmia, but the former usually occurring among girls at the time of puberty, without there having existed any of the well-recognized causes of anæmia, makes it reasonable to accept the theory that the disease is "symptomatic of functional disease in the sympathetic system of nerves." To state this view in other words: at the critical age of puberty, when a series of important and peculiar changes are being effected through the instrumentality of the sympathetic system of nerves, the system seems, in the female, to be liable to a morbid influence, which, in a great degree, paralyzes it and impairs its functions. Sadness, nervousness, and irascibility mark its onset; then neuralgia develops in the limbs, the head, and the viscera; the appetite is impaired; digestion becomes weak, and dyspepsia, flatulence and depraved tastes are encountered. The girl craves the most unpalatable and innutritious substances, as, for example, chalk, clay, slate, and other articles of an alkaline nature; while, at other times, the taste prompts her to consume acids, vinegar, lemon juice, pickled vegetables, etc. Usually, the process of blood-making is soon disordered, and anæmia sets in, coincidently with amenorrhœa, constipation, palpitation of the heart, sensitiveness along the spine, distress in the solar plexus of nerves, coldness of the hands and feet, and irregular and excessive flushing of the face (Thomas). Thus, it appears that one of the most aggravated expressions of indigestion and malnutrition, peculiar to young females, in all probability has its seat in, and exerts its influence through, the sympathetic system.

The complex nervous influence exerted upon the functions of digestion by a morbid condition of the uterus is one of the most ancient observations in medical practice. A diseased state, or a displacement, of this important organ sooner or later makes a decided impression upon the nervous system, and ultimately involves the general health. Likewise, ovarian disorders give rise to nervous disturbances, which, in time, are reflected throughout the entire system, impairing the functions of important organs It is probably safe to say that no other portion of the system suffers so much from nervous influences thus reflected, as do the stomach and intestines. As regards the stomach, when under such influences, its condition is often characterized by the most severe symptoms of functional disorder. Invariably there is either pain, persistent nausea, vomiting, pyrosis, loss of appetite, atonic dyspepsia and tenderness upon pressure. The intestines are also thrown into a morbid condition by irritation thus reflected, and, as a consequence, the patient suffers from distention due to accumulation of gases, as well as from constipation of the most persistent and obstinate character. To these brief allusions may well be added the significant words of a high authority. "With the exception of the last named state, which is, however, far more frequently associated with disorders of the stomach in weakly than in strong, healthy patients, there are few of the uterine derangements here enumerated which are not more or less associated with an impairment of the general nutrition. The majority also appear to be more truly connected, either as a cause or effect, with the primary disorder, than to arise wholly through the disordered digestion which is frequently the last in the series; while with respect to frequency, though not perhaps to severity, leucorrhœa and disordered menstruation hold the foremost rank among this class of causative conditions" (Fox).

Spinal irritation, or anæmia of the posterior columns of the cord, is another morbid condition of the nervous system which exerts a marked influence upon digestion. While sex, the female, seems to be the chief predisposing cause of spinal irritation, it is not improbable that in some instances the disease is due to depraved digestion and malnutrition of the nerve centres. But in any event, the seat of the disease is clearly traceable to the posterior columns, and manifests itself chiefly through the sensory nerves. The symptoms are of a character that locate the affection at the origin of the nerves of sensation, although the post-mortem evidences are only vaguely confirmatory. According to the law, "that irritation at a nerve centre induces pain at points in which the nerve arising from that centre end," when the cervical and dorsal nerves

are involved at their origin there will be disturbance in the region where the nerves are distributed. Hence, in a record of one hundred and forty-eight cases, *nausea and vomiting* appeared to have more relation to tenderness of the cervical spine, *pain of stomach* to tenderness of dorsal; but that, when there was soreness of both, *nausea or vomiting* was still more frequent, and *pain of the stomach* scarcely ever absent (Griffin). And again, in one hundred and fifty-six recorded cases an analysis showed that the dorsal region of the spine was tender in one hundred and sixteen. In thirty-seven of these it was conjoined with cervical, in nineteen with lumbar tenderness, and in fifteen it was affected with the whole spine, leaving forty-five uncomplicated cases. The most prominent symptoms in these cases were connected with the viscera, the *stomach* being the organ commonly involved. Thus, *gastralgia* was present in *every case*, *nausea* and *vomiting* in nine cases, *pyrosis* in three, *gastric flatulence* in forty, and *acidity*, as evidenced by heartburn, in twenty-six (Hammond).

Much more could be said in illustration of the place and power of nervous influences in the causation of indigestion. Furthermore, it would have been interesting to go into the pathology and the treatment of this line of cases, but space forbade. Enough has been said, however, to again call attention to certain manifestations of indigestion dependent upon, or associated with, marked disturbances of the nervous system, and, therefore, the object of this paper has been accomplished. The individual experience of nearly every practitioner, as well as many high authorities not herein referred to, would afford invaluable confirmation to everything to which an allusion has been made The observations and quotations set forth in this article are neither new nor novel, but simply tend to reaffirm the supreme importance of looking beyond the diet, the stomach, and the bowels, before making up a diagnosis of indigestion. The practical point in the treatment of most forms of indigestion is to seek out and correct the cause. This can only be done by bearing in mind that there are a multitude of causes, and that many of them are only discoverable to him who makes diligent searches in the labyrinths of obscurity.

CHLORAL HYDRATE.

BY H. H. KANE, M.D.,
Of New York City.

ANTISEPTIC AND DISINFECTANT PROPERTIES.

As an antiseptic and disinfectant chloral has achieved considerable success.

Dr. J. A. Larrabee[1] (Louisville *Med. News*), says, that when he took charge of the Forest Hill Lying-in-Hospital there had been four deaths within a few days, from puerperal fever. Carbolic acid had been used in extenso, without any benefit. He substituted chloral water, and there have since been thirty-nine deliveries without trace of fever. Uses a local wash to vagina and uterus, with result of at once correcting all offensive odor and stopping putrefaction.

Dr. P. H. Watson[2] writing to Dr. Craig, says:—

"I have in my wards (Edinburgh Royal Infirmary) used chloral hydrate for fully six months, and find it quite as active an antiseptic as carbolic or boracic acid." Its odor, unlike that of carbolic acid, is not disagreeable, and its vapor penetrates everywhere.

Dr. E. G. Coleman[3] used a solution of the strength of ℥ ij to Oj, as a disinfectant in a case of smallpox. with excellent result.

Dr. Guido Tizzoni[4] commends it for these purposes in surgical cases, as does also Dr. W. W. Keen,[5] surgeon to St. Mary's Hospital, Philadelphia.

In referring to some of its surgical uses Dr. Keen says that in many cases after operations in paraplegia, incontinence, etc., the urine has to be collected in a cup, or other vessel, and in spite of every possible care, even in private practice, the vessel soon smells, and the urinary odor, especially in summer, is often very offensive, as well as deleterious to health. In several cases I have tried the plan of putting a few grains of chloral into the vessel whenever emptied and replaced; from that moment the room and even the bed, bedding and vessel, were absolutely freed from all odor whatsoever. It would prove, also, I think, a very valuable agent for injection into the bladder in cases of retention, or inflammation, etc., in which there is any decomposition of the urine.

Tizzoni[4] and Fogliata[5] have used it for the same purpose.

[5] *American Journal Medical Sciences*, July, 1875, and Philadelphia *Medical Times*, March 21, 1874.

Dujardin Beaumetz[1] has found it serviceable in arresting putrefaction and fermentation.

J. W. Slinker,[2] of Mt. Ayr, Iowa, a solution of the strength of v–x gr. to ʒj, to inject and disinfect abscess cavities.

Siredey[3] uses for the same purpose the following:—

℞. Tr. eucalypti,
Chloral hydratis, āā ʒj
Aquæ, ℥j.

Vidal[4] has used it to preserve morphia solutions, intended for subcutaneous use.

Prof. Fillippo Pacini[5] prepares suspected blood stains for the microscope by immersing the matter in a solution of chloral hydrate (1 10 water). The corpuscles are softened without being disintegrated.

Dr. W. W. Keen,[6] of Philadelphia, has used it for preserving pathological specimens. The solution employed was of the strength of 40 gr. to ʒj. He also finds it an excellent embalming substance. To prepare subjects for dissection he injects the solution into the blood-vessels. He finds,[7] however, that bodies thus treated do not keep longer than three weeks, in warm weather.

He quotes Drs. Morris Longstreth and J. G. Richardson as saying that it is a perfect preservative for pathological specimens. Also Drs. Francis White, John H. and Joseph N. Dickson, as to its efficacy in preserving bodies for dissection. Also Dr. Wm. Macpherson, as to its power in preserving solutions of atropia, strychnia and morphia, and he has confirmed these results himself.

At Dr. Keen's request, Dr. Henry Leffman experimented on urine with chloral hydrate, and found that the only tests with which it interferes are those for urea and sugar.

Cruvelhier[8] showed to the Société de Biologie, the carcase of a dog whose carotid had received an injection of twenty-six drachms of chloral in a pint of water. Fifty-five days had elapsed, and there was not the slightest sign of decomposition.

Mr. Stoddart[9], of Bristol, has recently examined the stomach, lung, heart, kidney and spleen of a patient who died from an overdose of chloral hydrate. The first thing, he says, that struck me was the very extraordinary way in which the several portions were preserved. Even now, although more than a week has elapsed since death, yet not the slightest sign of decomposition has taken place, nor any unpleasant odor. This, doubtless, is the effect of chloroform in the tissues.

Mr. Francis Ogston, Jr.,[1] noticed the same peculiarity.

Jacobson[2] found that chloral had antiseptic properties; one half of one per cent. added to a concentrated solution of albumen (equal parts dry albumen and water), prevents decomposition for a long time. The same properties were noted by Personne[3].

Ortega[4] found great relief follow the use of a chloral wash (1–100) in a case of profusely perspiring, ulcerated, and foul smelling feet. His fellow workmen refused to be employed near him, owing to the terrible stench arising from the feet. The bad odor was soon relieved by the wash, but whether the man fully recovered cannot be said, as he passed from Ortega's notice, having been sent to another town by his employers.

In a case of gangrene of the arm in a young man, due, probably, to embolism, Dujardin-Beaumetz[5] kept the limb in a chloralized bath for twenty days, at which time amputation was performed by Verneuil, and the wound healed rapidly.

Massola[6] has used a chloral solution of the strength of 1–'00 to wash out the pleural sac in empyema. He advises gradual increase in the strength of the solution, never going beyond 50–100. Dujardin-Beaumetz and Villemin have used the drug for the same purpose.

Prof. Thaddeus Reamy,[7] of Cincinnati, recommends its use for syringing out the vagina after the operation for restoring a ruptured perineum.

CHLORAL IN TETANUS INFANTUM.

Prof. J. Lewis Smith[8] says of the use of chloral in this disease: "The remedy which, in my opinion, is far preferable to all others, is hydrate of chloral. Since the introduction of this agent into therapeutics it has been employed

by several physicians in the treatment of this disease, with so good a result that it will probably supersede all other medicines for this purpose."

I have been able to collect twenty-five cases thus treated, which resulted in fourteen recoveries and eleven deaths. A not very encouraging outlook at the first glance. When we consider, however, that heretofore this disease has been almost uniformly fatal, the prospect seems better. Dr. Smith's case was not seen until the disease was well advanced, and in some of the others the drug was not exhibited in sufficiently large doses. I think that at least six grains should be given every two hours to a new-born child suffering with this affection, until some impression is made upon the spasms, when the dose may be decreased. It must be remembered that children bear larger proportional doses than adults, and that this is an affection that calls for prompt treatment, its nature in most instances neutralizing the evil effects of this drug

Other means, such as keeping the bowels free, the navel clean and unirritated, and warmth and quiet, must not be neglected.

I have credited Wiederhofer with six fatal cases, the note from which I took the facts saying that he had six recoveries out of *ten or twelve* cases. I gave the mortality the benefit of the doubt, and credited him with six deaths when there really may have been but four. The success of this treatment is certainly reassuring. Under other methods of treatment all of Wiederhofer's former cases had died.

Considering that Vogel and other great German authorities on children's diseases, had quite recently never seen a case of this affection recover, such a success must be taken to indicate a real advance in therapeutics.

MEDICAL KNOWLEDGE OF THE NORTH AMERICAN INDIANS.

BY H. M. M'CLENAHAN, M.D., U.S.A.,
Of Montana.

Midwifery.

This, the third and last of the series, will be a general view of the subject of midwifery among the Indians. First in order will come pregnancy, with its diseases and accidents. Conception is dated from the time of the cessation of menstruation, that is, from the day on which menstruation should normally commence. The period of pregnancy is computed by moons, nine moons being considered the proper length of time. This would be considerably less than the average length of time, but some allowance should be made, and for two reasons: conception probably would occur several days before the one upon which menstruation would naturally commence; also in counting the number of days in nine moons, several days would be gained by beginning with a new moon and computing time until the waning of the ninth moon. It is impossible to get accurate data, for these Indians do not know the days of the week or month, so that I am unable to learn the exact period of pregnancy. The time of nine moons would be from 252 days to 267 days. As it is possible for the woman to have been pregnant about twenty days before the time they commence to count, we have as the limits in normal pregnancies 252 to 287 days, the mean time being 270 days. This average would be eight days less than that given in the books. But the data are too meagre to base reliable estimates upon. I have only heard of one case going over nine moons, that one extending over eleven moons. The number of cases of a less duration than nine moons are also rare.

The squaws are markedly free from the diseases incident to pregnancy. The only reason I know of is that their bodies are never distorted out of shape by wearing apparel. The clothing is worn loose, and a slender waist is unknown. They all perform manual labor and are muscular and well developed. Physically, they are stronger than the men. They ride "man fashion," and all ride horseback, too. During the first few months of pregnancy epistaxis is quite frequent, but never proves serious. Nausea and vomiting are rare occurrences, and are not persistent or serious. Never heard of or saw a case of albuminuria during pregnancy. The pregnant state does not in any way interfere with regular duties. They do not seem to give the subject any thought, simply taking it as one of the duties of life. Ordinary pursuits are followed up to the day of confinement; in some cases up to the very hour.

The women seldom abort, unless it be produced intentionally. Criminal abortion is sometimes practiced among them. The only way of producing it is by mechanical means. They have no medicine for that purpose, and so far as I can learn, they never produce it by operating through the vagina. Abortion is always produced before the fifth month, for two reasons: One is that the fœtus is not supposed to have life until that time; in other words, until the movements can be felt. It must be borne in

mind that until the fifth month means until the fifth moon. There is a notion among them that the fœtal movements are voluntary. In consequence, they will talk to and scold it, just as to an erring child. The second reason is that after that time there is danger to the mother, owing to the size of the fœtus. The ordinary manner of causing abortion is as follows:—

A stake is driven into the ground, leaving about two feet above the surface. The mother places the end of it against the abdomen, just over the womb, as nearly as possible. She then twists her body around on this, to kill the fœtus, as she thinks. If successful, uterine contractions result, with the desired effect. It is certainly a heroic treatment, and it would seem, one fraught with danger. Deaths, no doubt, do result, but I have not been able to learn of any. They would be slow, however, to divulge any facts pertaining to the subject. I do not believe they know abortion is morally wrong, and their love of maternity is not strong, so that a woman who has produced abortion neither sheds tears nor passes sleepless nights in anguish.

Those who have seen much of the Indians tell me they frequently kill the infants at birth. A favorite way of doing this is to let the child fall upon the ground when being born, either stunning it or breaking its neck. It is rather a sin of omission than of commission.

LABOR.

For this there is no elaborate preparation. No buying of flannels and muslins. No secret consultation between the old women of the neighborhood.

When the woman feels the pains coming on she repairs to the lodge, spreads a robe on the ground, and all is ready. She prefers to be delivered in a lodge. I have known of cases where the woman was living in a house and when about to be confined would go to a lodge. At this time they are very averse to whites being about. The whites might make bad medicine, that is, cast some spell over them by which evil would result to mother or child. Should any untoward symptoms arise they would be attributed to the whites, should any chance to be near. The medicine men do not attend cases of labor. That duty is relegated to the old women. There are always a few who have a reputation in such cases, and they are the ones sought after.

With the Indians there are no "stages" of labor. It begins with the first pain and ends with the delivery of the placenta, so I have no knowledge of the duration of the different stages. As a rule, labor is shorter than among civilized people. The shortest period of labor of which I have knowledge was two hours, the longest three days. Such protracted cases are, however, rare. From what I know and from the most reliable information, I should put the average duration of labor at four hours. The pains, they believe, are caused by the motions of the child. It thinks the proper time has come to move.

THE POSITION ASSUMED DURING LABOR.

So far as I know, without exception, they assume one position, that is the genu pectoral, as nearly as can be expressed. To be more minute, the woman takes a position on her knees, with the thighs widely separated. She leans forward, resting her head in the lap of an assistant, or a pole is suspended across the lodge, about eighteen inches from the ground, and she holds to it for support. They do not assume this position until the pains are severe, or until the second stage. During a severe pain some one will press on the lower part of the back. This affords them much relief. It is seldom that the fœtus presents by any other part than the head All other forms of presentation are the result of some evil spirit, and presage trouble to mother or child. Between pains the patient will move about, but never lays down. The child when delivered is not disturbed until the placenta comes away; this follows very soon. If it does not come as soon as it should, traction is made on the cord. No vaginal examination is made at any time. When the placenta is delivered the cord is tied near the body of the child and cut between the knot and placenta. I have no personal knowledge of a patient dying during labor. Yet, others report to me such cases. From these reports it seems probable that death was caused by retained placenta and post-partum hemorrhage.

MANAGEMENT OF CHILD.

As soon as the cord is cut the child is taken and wrapped up in a "meokeep." It is not washed, and if it be born in winter will not feel water until the following summer. Neither is it dressed. The meokeep, is a sack open at the top and laced up in front, and large enough to completely envelop all the child but the head and face. It is lined with soft cloths, and padded with the fir of thistle, or other soft material, to absorb the discharges. The child is put in this, laced up, and laid away until called for. The smegma, after drying, forms a thick layer over the head, which is believed to protect the fontanelles from injury. The child is soon put to the breast. The after birth is wrapped in raw hide and hung in some tree. It is a notion among

them that some harm would result should any animal devour it. The after treatment of the mother is very simple. A few hours after delivery she is allowed to walk about. In some cases, when the woman is confined while the camp is moving, she only rests a few hours, and then moves with the camp, either walking or riding horseback. Though, if possible, the rule is to take no exercise of any active kind for four days. During this time she is not to go near a fire, for the reason that it might excite a fever. From the history of some cases, I judge puerperal peritonitis or metritis occasionally occur, and invariably result fatally.

The lochial discharge is quite profuse for the first four days, and, they tell me, ceases at the end of the eighth day. This I do not think is absolutely correct, but after that time it is so small in amount as not to cause any inconvenience, and therefore no attention is given to it. Ablutions are seldom performed. The discharges dry on the thighs, form scales, and finally drop off. Nothing is worn next the vulva, either after confinement or during the menstrual period.

The women carry the children on their backs. A heavy leather strap encircles the waist, it being over the blanket and forming a bottom, upon which the child rests. The infant is then placed between the body of the mother and the blanket. The blanket is then drawn closely over the child, and fastened about the shoulders. The mother can then go about her duties, cutting wood, carrying water, etc., with the greatest of ease. Frequently you will see the babes sound asleep in this pocket while the mothers are working about. I am told of a case where an infant died while on its mother's back, unknown to her. While in the lodge, a sort of hammock is stretched across the lodge, in which the babe is placed. This can be swung to and fro, lulling the little pappoose to sleep, and is, I think, an improvement on the cradle used in civilized life.

LACTATION.

Indian children are usually well nourished, and where they are anæmic it is not from want of breast milk, but from some constitutional disease. As to how often they take the breast I am not prepared to say, but my observation leads me to believe that the child is the ole judge, for whenever it cries it is offered the breast. That is the only soothing syrup it ever receives.

There is no time for weaning. In many cases a child nurses until another one comes along. Even then it is slow in giving up, and it sometimes happens that a mother will nurse two children of different ages at the same time. The squaws are not remarkably prolific, but they all contribute their share of children, so that the average number of children for a given number of women is probably as great as among whites. Thirteen is the greatest number of children of one mother I have ever heard of.

Children are not named. Frequently no names are given until they arrive at the adult age. The manner of naming is peculiar. For example, if a boy falls into the river and swims out he is called the "swimmer," or if he sees some animal he is called by the name of that animal.

Medical Societies.

THE AMERICAN MEDICAL ASSOCIATION—32d ANNUAL MEETING.

The abstract of the proceedings given below is made up from the daily edition of the *Virginia Med. Monthly* and the *Public Ledger.*

First Day—Tuesday, May 3, 1881.

The American Medical Association met in its thirty-second Annual Session, at 11 o'clock, A.M., at Mozart Hall, Tuesday, May 3d, 1881.

The Association was called to order by Dr. Frank Cunningham, chairman of the Local Committee of Arrangements.

Dr. H. D. Holton, of Vermont, Vice President of the Association, occupied the chair, with Dr. William B. Atkinson, of Philadelphia, Pa., Secretary.

The exercises opened with prayer by the Right Rev. Bishop J. J. Keane.

Dr. Cunningham then, in brief and appropriate language, introduced Governor F. W. M. Holliday, who delivered the address of welcome.

At 12 o'clock, M. Vice-President Holton introduced Dr. John T. Hodgen, of St. Louis, the President of the Association, who proceeded to deliver his annual address.

He alluded to the progress in medicine, and then proceeded to bestow a passing glance upon some of the causes which militate against the success of the surgeon by sometimes betraying him into error, again embarrassing him in his choice between conflicting plans of treatment, and too often frustrating his best directed efforts.

He divided surgeons into those seeking to perform every practicable operation, and those avoiding operations whenever it is possible.

A simple knowledge, however accurate, of the parts involved, does not qualify one to make an intelligent prognosis, to decide upon the advisability of an operation, or treat judiciously even such diseases as consist mainly in pathological changes in the part in question—to say nothing of the many cases in which subjective symptoms are referred to a particular part, when they are in fact, but the local expression of some remote or possibly constitutional trouble.

Herein lies a danger which threatens the profession, through the adoption of exclusive specialties by those not well trained in general medicine. It cannot be denied that the early and exclusive study of the affections of a part tends to narrow the intellectual grasp and cramp the powers of the man who yields to the influences incident to such partial training. In the best sense, a specialist is a physician and something more; in the worst, he is something else and something less than a physician.

The rapid progress made of late years in the precision and perfection of regional surgery, the brilliant triumphs secured, and the almost unlimited possibilities attained, combined to tempt surgeons to reckless operative procedures. Captivated by the knowledge that almost every region of the body has been and therefore may be invaded without necessarily destroying life, we are in danger of overlooking the general influences which are ever present to modify and control the results of local injuries.

The local conditions calling for surgical operations are, besides, more easily studied by the young surgeons than the general conditions, which may forbid them, and are more fully discussed in the text-books and college lectures. To learn what to do and how to do it is always more attractive to the student than to be told what not to do. And this is especially true if the thing not to be done is something which he believes he can do well.

On the other hand, we recognize certain diseases and conditions, in which, however defective our knowledge may be in some respects, we are at least certain that very early operation is indicated, both as involving a minimum of risk, and as offering the best, or perhaps, only chance of saving life or of averting great calamity. In this class we include tumors, benign or quasi-malignant.

The propriety of the early removal of quasi-malignant tumors is nowhere better illustrated than in the case of sarcoma of the choroid—a disease which, by the aid of the ophthalmoscope, can now be positively and accurately diagnosticated at a very early stage of development. Left to itself for a few months, it will surely break through the outer coat of the eyeball, and soon develop into a fatal and hideous tumor of the orbit, complicated probably with sarcomatous deposits in distant parts. Removed at an early stage, by enucleation of the eyeball, it may never return *in situ*, and life may be indefinitely prolonged.

In rodent cancer and in epithelioma we now expect a cure by excision, provided it is done early enough; and even in mammary scirrhus, removal of the breast has exceptionally effected a permanent cure.

Sympathetic ophthalmia affords a striking instance, which may result either from not recognizing a danger in season, or from a want of promptness in dealing with it.

Scarcely any fact is better established than that a high condition of health is not the condition which best fits the patient to bear the forced confinement, the impaired digestion, the imperfect assimilation and the perverted excretion which follow any serious bodily injury or grave surgical operation. In such patients we have learned to dread surgical fever and active inflammatory complications, leading possibly to septicæmia, and ending, it may be, in death.

So, too, that standard of health marked by an unusual ability to bear continuous mental strain, taxing the digestive and assimilative organs to their utmost, is not that under which the effects of shock are best borne, whether it be the shock of a severe injury or of a capital operation.

On the other hand, a man whose life is not marked by excessive tissue change, whose digestive, assimilative and excretory organs are not unduly taxed, and whose nervous system is not attuned to conditions of intense mental strain, is likely to bear well the shock of injury and the nutritive changes incident to prolonged confinement. Again, the chronic sufferer, whose nutritive and excretory organs have become educated, so to speak, to make good the excessive waste incident to any continuous drain, is often much better fitted to endure a grave surgical operation than is the new recruit of the army of sufferers. Very often the surgeon is compelled to act in the presence of morbid conditions of the most complex character.

REPORT OF THE FOREIGN DELEGATES.

Dr. Joseph H. Warren, of Boston, Chairman of Committee of Foreign Delegates Abroad, presented his report. The reading of the report was deferred, and it was referred to the Publication Committee.

A portion of it was devoted to the advocacy of establishing a journal, to be published under the control of the Association, in place of the annua volume of Transactions.

In conclusion, Dr. Warren expressed it as his opinion that many young men of high intellectual abilities, who are now deterred from entering upon the study of medicine by the success which quacks are allowed to attain, because of the want of harmony and united action in the free exchange of opinion, would be encouraged to enter upon a professional life by the enthusiasm and spirit of harmony displayed in favor of scientific study, and in opposition to imposters and impositions.

After announcements by the Secretary of meetings to be held in the afternoon, the meeting adjourned until 10 o'clock next morning.

Second Day.

A large number, both of delegates and citizens, were present.

Rev. Joshua L. Peterkin, D.D., opened the session with prayer, and, after the announcement of the Committee on Nominations for Officers, the amendment to the Code of Ethics was considered.

A PROPOSED AMENDMENT.

The amendment provides that it is derogatory to the interests of the public and honor of the profession for any physician or teacher to aid, in any way, the medical teaching or graduation of persons, knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine.

Dr. Edward S. Dunster, Professor in the Uni-

versity of Michigan, made a long speech in opposition to the amendment, on the ground that it is contradictory to the letter, in many places, and also to the general spirit, of the code as is now stands; that it is illogical, and, in its reasoning, discreditable to the scholarship of the Association; that it is now, and must, of necessity, always be inoperative, not only as a matter of every-day practice, but also by reason of certain well defined legal limitations, in which the Association is without jurisdiction; that it is based upon a fallacious assumption, to wit: that teaching truth and science tends to build up and strengthen irregular and exclusive systems of medicine; that to establish the principles embodied in the amendment, that truth in medicine must not be taught to unbelievers, would prevent the teaching of truth in any department of human learning to skeptics and unbelievers; that the experiences of history are clear and convincing, that error, slowly, it may be, but surely, disappears before the promulgation of truth; that it is a part of the old-time policy of intolerance and persecution, whose only effect will be to build up and strengthen sectarian medicine; and finally, that, by the proposed course, we lay ourselves open to the charge of a want of faith in our own system, and confess our inability to compete with a school of medicine which we believe, both in theory and practice, to be largely based on error, or at all events, to state it as mildly as possible, on a misconception of the truth.

The further consideration of the subject was postponed, and made the special order for to-morrow.

ADDRESS BY DR. PEPPER.

After the reading of special papers, Dr. William Pepper, of Philadelphia, was introduced, and read a paper on the practice of medicine. He devoted himself to the consideration of the great importance of local lesions, and especially catarrhal inflammation of mucous membranes, as forming the essential cause of many apparently obscure diseases, and also as adding greatly to the danger of many diseases which are now regarded as due exclusively to the presence of some specific poison in the blood. He dwelt on the present tendency, which he thought exaggerated, to assume the existence of blood poisoning, and on the injury that is apt to result in practice, from regarding disease in so many instances as a special self-limited process, pursuing a definite course and practically uninfluenced by remedies. This theory will lead to dependence on a merely supporting and inactive treatment, and to the neglect of that minuteness in looking for and treating local affections that is so essential to the highest practical success. He illustrated this especially by reference to typhoid fever, dysentery and rheumatism. Allusion was also made to the importance of seeking for remedies possessing special antidotal powers against the great epidemic and contagious diseases, such as diphtheria and the eruptive fevers. In a few instances such specific remedies have been discovered, and allusion was made to the remarkable results that have recently been observed in the treatment of grave cases of diphtheria by the use of large doses of bichloride of mercury given in a special method. Without accepting these results as conclusive, they must be regarded as most encouraging.

The Doctor then discussed the large part played by chronic irritations of mucous membranes in the production of nervous disturbances and the impairment of vital power. Ample illustration may be drawn from dyspepsia, and from intestinal irritation. And again, as to the part played by such chronic irritations in keeping up a peculiar obstinate fever, which resists all treatment until the local trouble is removed; such cases are not rarely mistaken for malarial fever, and the excessive use of quinine in such cases is not rarely irritating and mischievous; and finally, such local catarrhs may produce morbid accumulations that may undergo changes and infect the system with the most fatal poisons. The most frequent and important instances of this are found in the development of pulmonary consumption from neglected or imperfectly cured catarrhal affections of the lungs. An attempt has been made to show that pulmonary consumption is a self limited disease, whereas, in truth, if placed under suitable treatment, hygienic and medicinal, at an early stage, it can be largely controlled in very many instances. The address closed with a renewed assertion of the excess to which the modern theories of specific poisons have been carried, and with the expression of the hope that ere long a system of medical thought and teaching will be developed, more truly practical, national and American, and less under the influence of speculative views that do not accord with the requirements of our medical practice or the results of our clinical observations.

PUBLISHING TRANSACTIONS.

Dr. John Packard, of Philadelphia, presented the report of the Committee on Journalizing Transactions. The report closed with the recommendation that a committee of five be appointed, whose duty it shall be to digest and report in detail, as early as possible, a plan for the publication of a weekly journal by the Association, the nomination of an editor, his salary, and the time and place of publication of such journal. The resolution was so amended as to leave out the nomination of an editor; the committee was increased to seven, and the resolution adopted.

Third Day.

This day's session was opened with prayer by the Rev. W. E. Hatcher. After the announcement of the names of additional delegates, papers on surgery and the results of the tenth census, as regards mortality statistics, were read by Drs. McGuire and Billings.

Dr. N. S. Davis submitted a report on "Clinical Observations and Records." The report was accompanied by a recommendation that a Committee of five be appointed by the President of the Association, to be called the Standing Committee on "Atmospheric Conditions, and their Relation to the Prevalence of Diseases;" also suggesting how the Committee shall be appointed, etc. The recommendation was adopted.

Dr. Stone submitted the report of the Committee on nominations, as follows: For President,

J. J. Woodward, United States Army, of Washington. First Vice President, I. P. O. Hooper, of Arkansas. Second Vice President, Laertes Connor, of Michigan. Third Vice President, Eugene Chisholm, of North Carolina. Fourth Vice President, Hunter McGuire, of Richmond. Secretary, William B. Atkinson, of Pennsylvania. Treasurer, R. J. Dunglison, of Pennsylvania. Librarian, William Lee, of Washington, D. C. Chairman of the Committee on Arrangements, Dr. Stone.

Vacancies in the Judicial Council were filled by the appointment of Dr. S. N. Benham, of Pennsylvania; Dr. J. M. Jones, of the District of Columbia; D. A. Linthicum, of Nebraska; William Brodie, of Michigan; H. D. Hollon, of Vermont; A. B. Sloan, of Missouri; and R. Beverly, of Colorado.

St. Paul, Minnesota, was selected as the next place of meeting.

The amendment to the Code of Ethics, article 1st, paragraph 1st, adds: "And hence it is considered derogatory to the interests of the public and honor of the profession for any physician or teacher to aid in any way the medical teaching or graduation of persons knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine."

Dr. Davis made an earnest speech in support of the amendment. He was followed by Dr. H. P. Martin, of Massachusetts, also in support of the amendment.

A motion to lay the subject on the table was lost—ayes 106, nays 108. The matter was then made the special order for next day, immediately after the meeting of the Association.

The following amendment to the by-laws, offered by Dr. J. M. Keller, of Arkansas, then came up and was adopted:

"In the election of officers and appointment of committees of this Association by its President, they shall be confined to members and delegates present at the meeting, except in the Committee of Arrangements."

Fourth Day.

The fourth and last day of the Association was opened Friday morning, with an eloquent prayer by Rev. Chas. H. Read, D.D.

The President announced the following Committee on Clinical Observations and Records: Drs. N. S. Davis, Chicago; J. M. Toner, D. C.; H. A. Marcy, Boston; W. H. Gedding, N. C., and S. M. Bemiss, New Orleans.

THE ETHICAL AMENDMENT.

Dr. Billings, of the U. S. Army, of Washington, submitted the following as a substitute for the amendment to the Code of Ethics, which was under discussion Thursday: "It is not in accordance with the interests of the public or the honor of the profession, that any physician or medical teacher should examine or sign diplomas or certificates of proficiency for, or otherwise be specially concerned with the graduation of, persons whom they have good reason to believe intend to support and practice any exclusive and irregular system of medicine."

Dr. Billings, in offering the paper, said: "This amendment has been prepared after consultation with the representatives of the various views which have been presented here, and it is believed to embody the prevailing opinion of the Association. It places no restriction upon teaching or upon the diffusion of knowledge, while it affirms the principle that we will not endorse in any way, or recommend to the public, men who limit their practice to one special dogma, or who deliberately class themselves with the villifiers of and sneerers at regular medicine, for the sake of notoriety."

The substitute, under the call of the previous question, was adopted.

The Committee on Nominations made their final report, naming the Presidents and Secretaries of the various sections.

ABUSE OF MEDICAL CHARITIES.

The Committee to which was referred the communication from Philadelphia County Medical Society, in reference to the abuse of medical charities, report that the proposed plan of co-operation between the medical charities and Philadelphia Society for Organizing charities is admirably adapted, if faithfully carried out, to remedy the evil at which it is aimed, and which has reached such colossal proportions in that as in every large city, both in this country and in Great Britain. As Philadelphia is exceptionally favored in having its systems of charity so admirably methodized and coördinated, your Committee would suggest that in other cities not possessed of this machinery, a concerted action of all the medical charities in combination with the police authorities, in the matter of the visitation and registration of the dependent classes, might be attended with valuable results. The report concluded with the following resolution:—

Resolved, That the Secretary be instructed to convey to the officers of the Philadelphia County Medical Society the acknowledgment of the indebtedness of this Association to the Society for thus bringing to our notice its action in a matter so nearly concerning the dignity of the profession and the welfare of the public.

USE OF PATENT REMEDIES.

The following resolution, after some discussion, was referred to the Judicial Committee, to report at the next meeting:—

Resolved, That the spirit of the Code of Ethics forbids a physician prescribing a remedy controlled by a patent, copyright or trademark. This, however, shall except a patent upon a process of manufacture or upon the machinery for the manufacture. *Provided*, the patent be not used to prevent legitimate competition, and shall also except the use of a trademark used to designate a brand of manufacture. *Provided*, That the article so marked be accompanied by working formula, duly sworn to, and also by a technical name, under which any one can compete in the manufacture of the same.

MORTALITY STATISTICS.

Dr. Billings, of the U. S. A., of Washington, D. C., read a paper on the improvement in the mortality statistics of the United States, as returned by the tenth census. Registers for recording deaths were sent to over 70,000 physi-

cians in the country, and answers were received from about 25,000. The largest proportion of physicians answering were from Pennsylvania, New York and Rhode Island. The first rough count shows about 620,000 deaths as returned by the regular gatherers of the census, but the returns from the physicians show an increase over this of about 50,000. An attempt has been made, in the tenth census, to obtain the number of the population on the 1st of June who are so sick or disabled as to be unable to pursue their ordinary avocations, and also to give the cause of such sickness or disability. This attempt has never been made before in this country, and in other countries has only been systematically made, as far as I am aware, in the three censuses of Ireland for 1851, 1861 and 1871.

It is too soon yet to speak of the results of this attempt, as the computations have not yet been made, but it is evident that either the returns will prove to be too imperfect to be of much if any statistical value, or the amount of sickness is much smaller than has been usually supposed. Taking the State of Rhode Island, where the census was taken under the direction of a skilled superintendent, Dr. Snow, who had so small a territory to deal with that he could make sure of the knowledge and training of almost all his enumerators, and where it is to be presumed the population schedules have been filled out with the greatest accuracy and completeness, it is found by a count that the number reported sick and disabled, aside from those reported as blind, deaf and dumb, insane, crippled, etc., was a total of 3276, out of a population of 276,528, being in the ratio of 11.8 per thousand. Comparing this with the results of the Irish census of 1861, I find that the proportion of sick at their own homes, reported in Ireland, varied from one in 142 to one in 942, in the different localities specified, which is in the ratio of 7.04 and 1.06 per thousand, respectively. It is usual to compute that for every case of death in a community, there are two cases constantly sick. It will be seen, if the estimate is correct, the Rhode Island census comes much more near completeness than that of Ireland. The only other source of comparison which I have thus far found available, is that of the health of the army, in which I find that among the white troops for the year 1877, the average number constantly on the sick roll was 44 per thousand of mean strength. Upon the whole, it seems probable that the results from the Rhode Island count are nearer the truth than any other data which we possess.

After the adoption of resolutions of thanks for the hospitalities extended, the convention adjourned, to participate in an excursion over the Richmond and Allegheny Railroad.

Proceedings of Sections.

State Medicine.—Chairman, Dr. J. T. Reeve, of Wisconsin; Secretary, Dr. R. G. Jennings, of Little Rock, Arkansas.

Papers were read by Dr. Billings, on "Some of the Results of the Tenth Census, as Regards Mortality Statistics," and on "Cellars," by Dr. A. N. Bell, of New York city.

Surgery and Anatomy.—Chairman, Dr. Hunter McGuire, of Virginia; Secretary, Dr. Duncan Eve, of Tennessee.

Dr. Joseph H. Warren, of Boston, Massachusetts, opened the work of the Section by exhibiting a collection of instruments devised by himself:—

First. A few vermicular-pointed catheters of three sizes. They combine the advantages of a screw and wedge, and its use is attended with less irritation and less difficulty of introduction. The next was his modification of Sir Henry Thompson's tube. It consists in having a tip, one-half of which is thrown back by a spring after it has entered the bladder. It acts as a scoop and allows of a free passage of the fragments. The tip may be made to revolve, or be stationary. The straight tube used by Bigelow may be made with this tip. It may be used to remove balls from gunshot wounds, foreign substances from nose, throat, or ear; for these cases smaller tubes may be used. A third instrument was a Bigelow's tube with a vermicular point. Much larger tubes of this sort with less shock are passed. Many of the dangers of large instruments are overcome by its use. The writer names this the Thompson American Tube, in honor of Sir Henry Thompson. The next shown was a uterine probe with revolving point. This has a fenestrated opening which can be threaded with a tuft of cotton. The next were a set of rapid dilating urethral and uterine sounds with revolving bulbular points, and also may be used for œsophagus and anus. The next was a trocar with revolving point—useful for tapping cases of general anasarca, etc. The next was a serrated herniotome; hemorrhage with its use is less. Dr. G. Bird's Torsion Forceps were also exhibited. Also, a self-retaining trocar, for paracentesis thoracis. The next was his latest devised hernia syringe, and finally an instrument called the Demonstrator's Knife—useful in dissecting veins, arteries and nerves. He also exhibited a modified sound, which he thought possessed many advantages.

Dr. Lewis A. Sayre, of New York, did not think the sound possessed anything to recommend it.

Dr. Gouley, of New York, saw no advantage in the rotary spiral sound—not even simplicity to recommend it.

Dr. Burchard reported an interesting case of ulceration of the appendix vermiformis, with remarks upon abdominal section in cases of perforation of the bowel. The writer took grounds strongly in favor of operative interference, and based his opinions on experience in many cases. Dr. Burchard advocated early operative interference in inflammatory affections around the cæcum. The operation is easy. An exploratory incision can be made for diagnostic purposes. Referred to acute perforating typhlitis. Thinks it should be divided into acute and chronic cases; the acute require surgical interference. Also has noticed some cases which appear to be recurrent. Thinks it better to stitch the intestine to the abdominal incision and make an artificial anus; and above all, thinks it our duty to give the patient the benefit of the operation with due antiseptic precautions. Dr. Burchard's remarks were

received with marked appreciation by the Section.

Dr. James E. Reeves, of Wheeling, West Virginia, presented for Dr. B. W. Allen, of Wheeling, a report of a case of pyonephrosis, exhibiting a nephritic calculus weighing 480 grains. The case was that of a widow, aged 55 years. Her general appearance was that of a great sufferer. She was sallow, emaciated, asthmatic and constipated. Her bad health dated from her menopause. On examination, a large tumor was found extending from the right hypochondrium to the left and pelvis. Fluctuation was marked. Aspiration evacuated 18 pounds of sero purulent matter, and this was followed by immediate relief. It was now found that the tumor had no connection with the liver, and the history of the case forbade the idea of its being ovarian. The benefit from the operation was only temporary, and death resulted. An autopsy showed a tumor extending from the under surface of the liver, with which it was in contact, but not adherent, downward into the cavity of the pelvis. The lower end of the ilium ran across the tumor to the ilio-cæcal valve, and producing a constriction noticeable before death. The sac was fifteen inches in length, twelve inches wide, and six through. It contained ten pounds of purulent fluid, and was found to be the remains of the left kidney. An enormous mal-connection was found imbedded in the sac together with smaller ones, weighing 416 grains. At no time were there symptoms of uræmic poison, and the other abdominal organs were healthy.

Diseases of Children.—Chairman, Dr. A. Jacobi, of New York; Secretary Dr. T. M. Rotch, of Boston, Mass.

The following is an abstract of the paper of Dr. H. I. Bowditch, of Boston, entitled "The Relation between Growth and Disease:"—

After discussing the various influences which must be taken into consideration in approaching this important subject, such as climate, race, social condition, occupation, and sex, Dr. Bowditch directed the attention of the medical profession to carrying out more extended observations on this subject, especially in the West, where the emigrant class, coming from different countries, present especial advantages for this kind of investigation. He also spoke of the intention of the Massachusetts State Board of Health, Lunacy and Charity, to distribute blank cards and circulars of instruction to aid in this work, and it is probable that the National Board of Health will soon undertake a similar work on a larger scale. Dr. Bowditch said that it seemed probable that the accurate determination of the normal rate of growth in children will not only throw light upon the nature of the diseases to which childhood is subject, but will also guide us in the application of therapeutic measures. The statistics of growth, taken in connection with those of disease, might very possibly reveal unexpected relations between periods of slow and rapid growth, and the ages at which certain diseases most frequently occur.

He referred to Dr. Percy Boulton's expression of "danger signals," in his paper on the weighing of children. Dr. Bowditch then exhibited a chart representing the case of a child, between two and three years old, where careful and systematic weekly weighing showed, first, the approach, by some weeks, of a chronic disturbance of nutrition, represented by enlarged cervical glands and clay-colored stools, and second, after recovery, the approach of an attack of measles, the "danger signal" of progressive loss of weight preceding the eruption by at least a week.

Dr. White, of Boston, presented a paper entitled "Some of the Causes of Infantile Eczema, and the Importance of Mechanical Restraint in its Treatment."

He first described the many and varied external influences which immediately affect the delicate skin of the new-born as being a common cause of eczema, and laid especial stress on the fact that heat was the more usual cause of the disease than cold. He said, however, that these external influences furnish but a small proportion of all the cases of the disease which occurred at this period of life, although by far the greater part of those concerning the etiology of which we have any positive knowledge. During the last twelve years he had treated, at the Massachusetts General Hospital, 5000 cases of eczema, of which 1770 occurred in children of ten years of age and under, and of which the largest proportion, viz., 569 cases, was in the first year of life. He said, eliminating the operation of the causes directly acting upon the skin from without, above mentioned, and a few other extraneous agencies, the parasitic chiefly, that he did not hesitate to say that he knew nothing whatever of the causes of the disease in the remainder; also, that as far as his experience went, eczema affected all classes of society alike, occurred at all seasons of the year, came in children of all degrees of health, in the perfectly sound as frequently as in the feeble; that it had no necessary connection with any other disease of childhood; that it showed itself in an equal proportion in bottle babies and those reared at the breast, and was independent of diet; also, that if there were other assigned causes, he would here say that his observation gave him no justification for believing any of them.

He stated that there was no more necessity for a supposed sympathy with, or dependence upon, the state of the blood, or the condition of some other organ, when the skin is affected with eczema, than when the lung, kidney, etc., is affected. He then, after speaking of the extreme suffering which the little patients undergo, said that the prime factor of the treatment was the prevention of scratching, and he described what he considered to be the proper method of controlling the child's movements, viz., a system of swathing in a pillow-case, by which the same chances of success in the therapeutics of infantile eczema is given as exist in the adult.

He finally said that when the strait-jacket treatment is carried out, the child soon becomes used to the confinement, and a wonderful improvement takes place, not only in the disease itself, but in the morale of the family, which always becomes painfully disorganized during the existence of the disease; and he mentioned, as an important factor in the success of the treatment, that a grandmother (if present), in every case of

infantile eczema, is the first evil to be eliminated. In conclusion, he considered that the simple mechanical means found in every household included all that was important in the treatment of one of the most distressing and rebellious diseases of infancy.

Dr. L. Duncan Bulkley regretted criticising the paper, as he felt obliged to do, in the absence of his friend, Dr. White, but the views presented differed so radically from those which he had formed from experience, that he could not help so doing, because he felt that the subject demanded it. For those who did not know of his acquaintance with the disease, he would state that he had recently made analyses of 2500 personal cases of eczema, and of these nearly 700 had occurred at an age which classed them as infantile eczema; he therefore believed that he could speak with authority on the subject. Dr. White had, it is true, treated of only one feature in the management of the disease, namely, physical restraint, but he believed criticism to be called for, because of the principles which underlie, or which call for this element of treatment; the premises being wrong, what follows must of necessity be wrong.

Dr. Ulrich, of Pennsylvania, in discussing the paper, said that he fully agreed with Dr. Bulkley, and that he entirely opposed Dr. White's treatment. In a long professional career he had never used a system of restraint in these cases, and that he would prefer to knock the little patient on the head at once rather than submit it to the tortures of Dr. White's straight-jacket.

Dr. H. O. Marcy exhibited to the Section some elastic double canular injection tubes, which he thought useful in various diseases. The tubes presented were of different sizes, to be used in inflammatory conditions of the uterus, bladder, rectum and bowels. They are not costly, easy to carry, and very serviceable. Dr. Gouley, of New York, asked Dr. Marcy if he claimed this a new device. Dr. Marcy replied that they were new to him. Dr. Gouley had certainly used the catheter years ago, and protested against the introduction of so many so called new and valuable instruments. Thought the next era would be time enough for more, and could not appreciate its great use in bladder troubles. Dr. Marcy thought there must be virtue in hot water in diseases of the bladder, as in diseases of the uterus. The stomach tube he feels much easier to introduce.

Dr. Wm. A. Byrd, of Quincy, Ill., presented a specimen of ulceration and perforation.

The following is an abstract of the paper by Dr. D. H. Goodwillie, of New York city, on Thumb Sucking, illustrated by the report of a case and exhibited by a wax model:—

Treatment consisted in breaking up the habit by applying a leather pad to the elbow, preventing the hand from coming to the mouth.

Nasal Catarrh by douches and the application of powder blown into the nose, proper food, clothing and rest.

His conclusions were as follows:—

1st. Thumb-sucking is more disastrous to the health of the child than the sucking of the other fingers, for the thumb, once in the mouth, it more readily remains during sleep.

2d. It interferes with the child's proper rest, which should be continuous and undisturbed, and so becomes a source of nervous irritation and exhaustion.

3d. It interferes with the natural respiration through the nose, and sets up abnormal conditions.

4th. It malforms the anterior part of the mouth, and affects proper mastication.

Opthalmology, Otology and Laryngology.—Chairman, Dr. D. S. Reynolds, of Kentucky; Secretary, Dr. S. M. Burnett, District of Columbia.

A paper was read by Dr. G. T. Stephens, on the *Perimeter*, invented by himself, for measuring the field of vision. Dr. Stephens described the instrument closely, remarking that most of the instruments hitherto used are very large, weighing a good many pounds, and consequently inconvenient for using. His instrument removes some of the difficulties. The gentlemen present were invited to examine the instrument.

Dr. W. C. Jarvis next addressed the meeting on the subject of "Nasal Catarrh with Hypertrophy." He remarked that the persistence of the disease is due to hypertrophy of tissue. This must be removed, and instruments are necessary to effect this result. The écraseur is the instrument employed. The wire used is very fine, but exceedingly strong, and made of the best steel. The transfixion needles are provided with metal handles, and are made of various sizes. The simpler forms of hypertrophies can be removed with the écraseur alone, but sessile growths require both. Dr. Jarvis stated that all degrees of hypertrophy can be removed by means of these instruments. In one patient, who had not breathed through the nose for fifteen years, and in one who had never breathed at all through the nostril, the relief was almost immediate. All kinds of nasal growths can be reached by means of the instruments, and there is no longer any use of resorting to caustics, cutting and the galvano-cautery.

Dr. Daly said the instrument was a very useful one. In his experience, deafness of greater or less degree has often been relieved by removal of nasal growths, and that, too, without treating the deafness at all. If the "central trouble" or hypertrophy be remedied, the result will be good. The galvano-cautery, used for a few moments at a time, is an excellent means of removing the growth in some instances. The finger is introduced into the pharynx as a support and protection. In some cases glacial acetic acid answers well as an application to the stump after the removal of the growth with instruments. Cases under his care have been watched for years, and have progressed favorably. In one case in which sessile growths were present, these were removed with the galvano-cautery, heated to a mahogany or cherry red. The apex of the growth disappears, gradually becoming hollowed out, and sound, normal structure is left. The surrounding structures are not injured.

Dr. Rigsby wished to know to what extent deafness is due to anterior nasal catarrh.

Dr. Jarvis said that the extent was undeterm-

ined, but that the pharyngeal trouble is secondary to the anterior disease. The acid secretions of the part flow backward and irritate the healthy mucous membrane. A mild astringent injection may sometimes give rise to the pharyngeal disease, and it is highly probable that the secretions of the part diseased can act in the same way.

Dr. Rigsby said he had been struck, after a long experience, with the connection between aural and nasal diseases. Deformities in the vomer and turbinated bones produce trouble in the ear, after giving rise to hypertrophy and sometimes ulceration in the nose. Deflection of the vomer to one side is one deformity giving rise to ear disease. Operative interference is not often needed. Iodoform, with alum, or acacia, is an excellent application. In other cases, where no deformity exists, the rhinoscope will reveal a group of enlarged glands. These give rise to a viscid secretion which irritates the surrounding structure.

Dr. Chisolm then read a paper on the "Treatment of Conical Cornea." He said that it is a pertinent question how to get the projection back. Suggestions had been made of cutting out a piece of the cornea and bringing the surfaces together. After reading a French article on puncture of the cornea with a needle heated to redness, he determined to put it into practice. A case of exophthalmic goitre with a complication of eye troubles, were selected; objects could not be distinguished one foot off. No anæsthetic was given, and the needle was thrust suddenly through the cornea. The anterior chamber was immediately emptied; no pain was felt; and atropia and cold water were used. There was no inflammatory action. As soon as the eyes were opened the patient read at six feet. The same operation was used on the right eye, and eight months afterwards the cornea was perceptibly flattened, sufficiently so to admit of an iridectomy.

Section on Practice of Medicine, Materia Medica and Physiology, met at 3 o'clock, P. M. Dr. Pepper being absent, Dr. J. A. Octerlony, of Louisville, was called to the chair, Dr. T. A. Ashby, of Baltimore, Secretary, being in place.

D. W. C. Wile, of Sandy Hook, Connecticut, read a paper upon "Blood letting as a Therapeutic Measure in Pneumonia." He said that it was with great hesitation he approached such a subject, but that, in the light of his past experience, he felt it to be his duty to do so. He could not, in the limited time at his disposal, say anything in regard to the etiology or diagnosis of pneumonia, but should confine his remarks to the consideration of a therapeutic measure. He then proceeded to say that, while he knew he was treading upon almost forbidden ground, and that he would meet with great opposition from the profession at large, he felt compelled to urge the importance of the *free use of the lancet* in pneumonia. He cited a typical case of what he called "Acute Catarrhal Pneumonia," in which he had recommended the abstraction of blood in the first stage, but in which, owing to the opposition of the family, he had been unable to carry out the practice he recommended until the disease had advanced to the second stage, but even then with the most marked and immediate favorable results. He entered very fully into the details of this case, as it was one of a class which had proved peculiarly fatal in Connecticut, under any treatment he had adopted; and reported a series of twelve other similar consecutive cases, with like favorable results.

Dr. John J. Lynch, of Baltimore, remarked that he thought, from Dr. Wile's description of his cases, that he had made a mistake in diagnosis, as they were evidently "*croupous*" and not "*catarrhal*" pneumonia. The Doctor was also probably mistaken in attributing the rapid recovery of his cases to the bleeding, because croupous pneumonia most frequently ends in from two to eight days, by sudden crisis, and Dr. W.'s cases would probably have recovered just as soon without the bleeding. Dr. L. admitted that for rapidly extending collateral hyperæmia in pneumonia, bleeding might be necessary, and was most efficient, but this was from the merely mechanical effect of the remedy, and in no sense curative. The disease would run its course afterwards, in spite of the bleeding.

He hoped he would never see the day when the profession will return to the sanguinary method of treating pneumonia less than half a century ago, when the average mortality was more than twenty-five per cent., while by the modern, purely rational method, it was, in uncomplicated cases, not more than four or five per cent.

Dr. Whittaker, of Cincinnati, said that he thought too earnest protest could not be made against this revival of venesection at this late period in the history of science. Pneumonia is now known to be a general disease with a local expression in the lungs, just as typho'd fever is a general disease with a local expression in the intestines. There could be no justification of venesection in pneumonia, except upon the theory of a local inflammation.

Dr. N. S. Davis, of Chicago, said that he had practiced medicine for nearly half a century, and that for fifteen years he had practiced venesection after the regular sanguinary method, and that he must say that he had found the best results from blood-letting in pneumonia, when discriminately employed.

Dr. Octerlony, of Louisville, Ky., said that he did not wish to discuss the general subject of pneumonia, but to offer some remarks in analysis and friendly criticism of Dr. Wile's paper. In the first place, he did not deny that cases are occasionally met with in which blood-letting is indicated and will prove beneficial in relieving venous congestion, but he did not think Dr. Wile's cases sufficiently numerous to establish a law, nor were they reported with sufficient care to make them available.

The first stage of the disease was the period during which Dr. Wile would have us bleed, because this was the stage of engorgement; but that he (Dr. O.) claimed that even at this period exudation had already occurred, as shown by the physical signs, dullness, absence of vesicular murmur and the presence of fine crepitant *râles*. Bleeding will not return this exudation to the vessels; this can only be accomplished by a vital process. The mortality in Dr. W.'s cases was 1 in 13, far greater than that resulting from the plan of *promoting the natural progress of the dis-*

ease and supporting the strength of the patient. The duration of his cases was not less but greater than our knowledge of the natural history of the disease shows to be the rule.

In conclusion, he must insist that the writer had not proved his proposition, viz.: that pneumonia is a very fatal disease, nor that the mortality or duration of the disease have been diminished by venesection. On the contrary, it seems to be a well established fact that pneumonia is a self-limited disease. The blood-letting plan of treatment used to give a mortality of 1 in 5. The purely expectant plan, 1 in 13. The plans he had here recommended gave, in Bennett's hands, a mortality of 1 in 36.

Dr. J. H. Claiborne, of Virginia, said that he did not think we could fail to go astray if we followed the teaching of the gentlemen who always recommended bleeding, nor could we fail to go astray if we believe those who tell us never to bleed. The middle course was safest, and we should be guided more by experience than by theory. There was no one method of treatment applicable to all varieties of pneumonia.

Dr. Post, of New York, said that in his opinion no dependence could be placed on statistics, as they were drawn from a class of patients found in hospitals, who had been badly clothed and badly housed and fed all their lives, and such statistics were not reliable guides. We must be guided solely by experience. He could not sympathize with the gentleman who expressed the opinion that the lancet could no longer be used in medicine, for he believed that when properly and discriminately used, recovery was more rapid after bleeding.

Dr. Coleman, of Vermont, said that theoretically he believed in the lancet in a certain class of cases, but that in practice he did not meet with that class of cases where the blood was being forced into the lungs so rapidly as to produce strangulation, as he was not called in time to see them in that condition.

Dr. Quimby, of Jersey City, said that in all acute inflammatory cases where he used stimulants he lost his patients. Under a modified treatment he had not lost a patient. In all cases where he had used the lancet he had done so on the first or second day. He thought we did not often see these typical cases in the very first stages. We cannot treat patients as if they were machines. He advocated the free use of the lancet, when properly and timely used.

Dr. Whitney, of New York, said that when he first commenced practice he had felt it to be his duty to bleed all cases of pneumonia; since then he had, to a great extent, abandoned the use of the lancet. But that he thought the mortality had never been so great before as since the abandonment of venesection. He thought we did not bleed half enough.

Dr. Ballou, of Rhode Island, had never used the lancet that he regretted it, but had often failed to bleed, and regretted it very much.

Dr. North, of Iowa, always carried a lancet; he had never lost a case of pneumonia, and had never yet bled one.

Dr. Jackson, of Virginia, thought it objectionable to speak of blood-letting as a treatment of pneumonia; we ought to speak of it as an adjuvant or auxiliary. It was wrong to let it go abroad among the younger men that we had either advised against or for blood-letting.

Dr. S. D. Gross belonged, he said, to the younger members of the profession. He had listened with deep interest to the remarks made here. Pneumonia was an inflammatory affection, and the lancet in such affections was applicable in young, robust and healthy subjects. Bleeding was not applicable in *all* stages of pneumonia, but only in the commencement, when the disease was in its infancy—not later. We employ bleeding simply as an adjuvant, and under such circumstances we employ it wisely. If, however, we wait until consolidation has taken place, bleeding does harm, no matter what be the form of pneumonia, whether croupous or catarrhal. If bleeding was performed in time, and on proper subjects, it was the great remedy in this disease.

Dr. Lester, of Michigan, did not think the practice of venesection so good as the theory. We did not bleed in cerebro-spinal meningitis, because we knew we should lose our patients; but we used the supporting treatment. He asked what was the difference between the two inflammatory conditions? He was surprised at so much advocacy of the lancet in pneumonia, and would like to see it dispensed with.

Dr. Martin, of Massachusetts, trusted that it might go out to the world that the American Medical Association sanctions the *occasional* use of the lancet, at least.

Dr. Wile, of Connecticut, in closing the discussion, expressed his gratitude for the courteous manner in which his paper had been discussed, and he accepted from the gentlemen their diagnosis of his cases. He felt delighted to learn that pneumonia was such a pleasant disease to treat as those gentlemen who proscribed the lancet seemed to think it. The cases he had reported were of the class, and the only class, he had met with in Connecticut. He did not wish to be understood as saying that the lancet was the only mode of treating pneumonia, but that it was the only way of treating those cases of pneumonia with which he had come into contact in Connecticut.

Section on Obstetrics and Diseases of Women.—Chairman, Dr. James R. Chadwick, of Boston. Secretary, Dr. Joseph Tabor Johnson, D. C.

Resumè of Rules for the use of Pessaries.—Dr. Paul F. Munde, of New York, made a brief recapitulation of the rules governing the introduction and supervision of vaginal pessaries (including vagino-abdominal).

1. Always be sure of the diagnosis of the nature and degree of the displacement before resorting to a pessary.

2. Always replace the uterus before applying a pessary. This applies particularly to retro-displacements. It is well to replace the uterus repeatedly, every day or twice daily, for several days before introducing a pessary. The replaced organ may be supported by cotton tampon in the interval, if it is desired to distend and toughen the vaginal pouch; or the object of relaxing the abnormally stretched uterine ligaments may have been obtained by the mere repeated replacement.

In flexions, chiefly ante-flexions, the frequent straightening of the uterus, or conversion into the opposite flexion by the sound, will often prove beneficial before introducing a pessary.

3. Never insert a pessary when there is evidence, by the touch, of acute or recent inflammation of the uterus or adnexa, or when pressure by the finger on the parametrium (where the pessary is to rest) gives decided pain.

4. When the uterus is not replaceable, that is, when adhesion binds the fundus down, use great caution and discrimination in deciding whether an attempt should be made, and is justified by the symptoms, to elevate the fundus by manual or instrumental means, or whether the elevation should first be tried by the gradual elevation of a pessary (this applies only to retro- and latero-versions). If neither is to be recommended, do not introduce a pessary until local alterative and absorbent measures have effected a resolution of the adhesions.

5. Always choose an indestructible instrument, if possible. This does not apply to prolapsus uteri.

6. Always measure and estimate the vagina carefully before choosing a pessary, and be careful to adjust the pessary in every particular (size, curve, width) to that particular case. No two vaginæ are exactly alike.

7. If the vaginal pouch is not sufficiently deep to accommodate a pessary (anterior pouch for ante displacements; posterior pouch for retro-displacements), defer the attempt to fit a pessary until the pouch has been deepened by daily tamponing with cotton, or by the upward pressure of a cutter or Thomas' vagino-abdominal supporter. Or the pouch may be gradually deepened by using first a small (slightly curved in retro displacement) instrument, and gradually increasing its size (or curve) until the desired size and shape for permanency is reached.

8. Never leave a pessary in the vagina which puts the vaginal walls to the stretch, and which does not permit the passage of a finger between it and the wall of the vagina. This does not apply to prolapsus uteri.

9. A vaginal pessary which projects from the vulva is displaced.

10. A pessary which gives pain must at once be replaced by one which is painless.

11. A well fitting properly-chosen pessary should not only give no pain, but should be a direct source of comfort to the patient.

12. Always examine a patient on her feet after introducing a pessary, or when it is desired, at her return, to ascertain its efficiency in sustaining the uterus during walking and exertion.

13. Always tell the patient that she has a pessary in her vagina, or she may not return, in spite of your directions, and the pessary may remain for years, to her ultimate great discomfort and danger.

14. Always tell the patient to return within a week after the first introduction, in order that the position and working of the pessary may be looked after, and that, if it does not suit, it can be removed and a better one inserted. Tell her that several trials and various instruments may be required before one is found which she can wear permanently. Also let her return for inspection once every four to eight weeks, as the case may require. Tell her that if she fails to do so the pessary may cause ulceration, for which treatment will be needed.

15. Tell the patient that she will need to wear the pessary for months, perhaps years, before a recovery can be expected.

16. Never introduce a pessary which the patient cannot remove herself.

17. Tell the patient to remove the pessary herself if it gives pain, and show her how to do it. When she has removed it let her present herself at once for examination.

18. Tell the patient to use daily vaginal injections, for cleansing purposes. If she notices profuse discharge, add astringents; if the discharge is sanious or purulent, let her come at once, as the pessary has probably caused abrasion.

19. Tell her, on removing a pessary, to test the result; that the permanence of the benefit obtained therefrom cannot be determined for several days or weeks.

20. Always direct your patients to relieve all superincumbent pressure on the pessary by a proper support of their skirts; and if the displacement be anterior, aid the internal supporter by an abdominal (supra pubic) pad.

All pessaries may be introduced in the knee-chest position, when it is desirable or possible to replace the uterus only in that position.

Editorial Department.

Periscope.

Angina Pectoris.

M. Paul Gerne presents, in *le Concours Méd.*, No. 8, 1881, an interesting study on this malady. Its history is short; described in a private letter to Lorry, by Rognon, in 1768, it received the designation it bears at present from Heberden, in the course of the same year. The patient is often seized in the full vigor of health, after too active exercise, a copious repast, sometimes without any appreciable cause. A terrible and constrictive pain is felt in the cardiac region, the patient feels as if torn by claws of iron (Laënnec), or seized in a vise. The pain irradiates toward the neck, the epigastrium, down the arm to the fingers. He remains immobile in whatever position he happens to be; there is no possibility of speech or motion. A terrible sense of impending dissolution comes over him, for, as Heberden says, he feels that there is a universal internal pause in the natural functions. Death may be immediate; if recovery takes place, after a few seconds or minutes there is diminution of pain and anguish; the face reddens notably

(Trousseau); all is dissipated, but there yet remains great lassitude, and the patient is dominated by his fears. Respiration is generally regular during the attack, but in some cases there is pulmonary congestion with intense dyspnœa. The pulse is sometimes irregular and intermittent; there is often palpitation, succeeded suddenly by marked slowness in the cardiac revolutions. In some cases (Bernheim, *Clin. Méd.*), the pain is absent, but there exists a disposition to syncope which may prove fatal. Many theories have been put forward regarding the nature of the affection; for French pathologists it has a nervous origin; excitation or paresis of the pneumogastric (Jaccoud), of the phrenic (Peter). For the English school there always exists some lesion of the heart or great vessels—ossification of the coronary arteries, atheromatous degeneration of the aorta, etc. The Germans, with Guttman and Eulenberg, with Landois and Nothnagel, regard angina pectoris as due to generalized arterial spasms, which obliges the heart to painful contractions in order to overcome peripheric resistance.

The theories regarding the influence of the pneumogastric have led to the employment of electricity over the course of the nerve (Laënnec, Duchenne, Onimus). Generally it will be proper to administer a strong injection of morphia at the moment of the attack, to be followed by a course of treatment applicable to whatever diseased condition may be present; bromide of potash and antispasmodics, when there is any hysterical or hypochondriac tendency, together with arsenic, which is a veritable tonic for the nervous system (Anstie, Handfield, Jones).

Inhalations of chloroform are often of benefit during the attack, but should be used with extreme caution if there is any cardiac lesion, as it sometimes of itself induces fatal syncope.

Hypertrophied Tonsils.

In a recent lecture in London, Mr. Christopher Heath stated that hypertrophied tonsils are liable to lead to the deformity known as "pigeon-breast," from interference with the full expansion of the lungs. The thick speech, open mouth, and stertorous breathing, which in sleep develops into sonorous snoring, are sufficiently marked in extreme cases; while, in milder cases, the constant tendency to sore throat, and the general failure of health and strength without obvious cause, should direct attention to the tonsils. On inspection, the tonsils will be seen as large, white, glistening masses, often meeting in the middle line, and presenting yellow spots due to inspissated mucous secretion. Hypertrophied tonsils may project into and down the pharynx, but can never reach up to and obstruct the Eustachian tubes, the deafness so commonly found in these cases being due to the generally congested condition of the mucous membrane, which is relieved by the removal of the glands.

The application of local styptics, in the form of a solution of nitrate of silver (gr. x to ℥j), or the glycerine of tannin; the use of catechu or krameria lozenges, or the employment of a spray of sulphate of zinc (gr. x to ℥j), are all useful in slight cases, by keeping the disease in check while the patient's health is improved by sea air and tonics. In severe cases removal is the best remedy, and is much less painful and infinitely more satisfactory than drilling the tonsil with a sharp stick of nitrate of silver or caustic potash, as has been recommended.

The simplest form of guillotine, used with a pair of vulsellum forceps, by which the tonsils can be drawn thoroughly into the ring with the opposite hand, is preferable to the complicated guillotines fitted with a fork, which are apt to get out of order, and require considerable practice for their successful employment. The patient being seated in a good light, with the head thrown back, and the hands held by assistants, the guillotine can be slipped into the mouth, which it immediately gags; the forceps then grasping the tonsil through the ring of the guillotine, draws it well forward, and a sharp movement of the thumb drives home the blade of the guillotine, and cuts it off. Without withdrawing the guillotine, it is turned around, and the other tonsil similarly treated by changing hands, before the little patient has really time to cry. It is quite sufficient to remove a large portion of a tonsil, and any attempt to remove the whole is likely to be followed by sharp bleeding. Ordinarily, the sucking of ice for a few minutes staunches all bleeding; but, if not, the bleeding surface, and that only, should be painted with liquor ferri pernitratis.

After removal of the tonsils, ice may be sucked for a few hours, and a warm poultice under the jaw gives great comfort. Care should be taken to give food cool enough to be easily swallowed, and for a few days, anything hard, such as crust, should be avoided.

The Treatment of Typhoid Fever.

In the *Practitioner*, March, 1881, Dr. F. A. McEwen, of Aberdeen, describes the plan which he pursued in an epidemic of typhoid fever, with very satisfactory results. It was as follows:—

In the great majority of the cases looseness of the bowels, with the characteristic evacuations, was present; but unless the diarrhœa continued distressing I generally allowed it to go on. When along with the looseness of the bowels there was restlessness and want of sleep, I found small, repeated doses of Dover's powder most beneficial in subduing the diarrhœa and inducing quiet repose. In a few of the cases, instead of looseness there was constipation with tympanitic distention. The constipation I never tried to obviate, and the bowels always acted in good time. One case in particular, where the patient remained ten days without having her bowels moved, made a very good recovery. During the whole time there was tympanitic distention, and a continual discharge of flatus; but at the end of the ten days the bowels were moved naturally. I confined my patients almost exclusively to milk, with a little lime-water or soda-water added. When the frequency of the pulse denoted great weakness of the circulation I gave from half an ounce to an ounce of good old Scotch whisky, three or four times a day; and the administration of this stimulant I invariably found to have a strengthening effect upon the action of the heart.

Sponging the body once or twice a day with tepid water was agreeable and refreshing to the patients, and was generally followed by a sense of comfort. When at all practicable I saw my cases twice a day; and in the absence of intelligent nurses I set myself to teach nursing, practically and theoretically, to the best of my ability, to those about the sick.

The Treatment of Phosphatic Diabetes

At the close of an article in the *Lancet*, March 19th, on this form of disease, Dr. C. H. Ralfe says:—

With regard to the treatment of the form of disease under consideration, the main indications are rest and endeavor to promote nutrition generally. To attain this end opium or codeia should be given in full doses, when the patient first comes under observation. As soon, however, as the nervous system is quieted, and the rheumatic and neuralgic pains are less severe, it should be discontinued, lest it interfere with digestion. General tonics, such as iron. quinine, nux vomica, hydrochloric acid. and cod-liver oil should be persevered with. When there is a history of syphilis iodide of potassium should be combined with these remedies. Warm baths, followed by tepid douches, give great relief to the neuralgic pains, and also soothe the nervous system. The soluble phosphates may be administered, but their utility in these cases is questionable. There appears to be no lack of these constituents in the system; the difficulty seems rather to lie in the want of power of the tissues to retain them. The food should be light and nutritious, and milk one of the chief constituents. Alcohol should be avoided; it invariably, even in small quantities, increases the diuresis. The same may be said of coffee. Change to dry, bracing air should be obtained, if possible. The clothing should be warm, and the patient carefully guarded against cold, since in these cases a reduction of bodily temperature is always noted. When, in spite of the pursuance of these therapeutic and hygienic conditions, the diuresis and excretion of phosphoric acid continues, though the general condition of the patient may temporarily improve, there is reason to fear that phthisis will supervene, or that the disease may assume the features of saccharine diabetes.

Reviews and Book Notices

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Wm. S. Little, of Philadelphia, in a reprint from the *Archives of Ophthalmology*, gives some examples of the practical advantages of color blindness, and some observations on this defect, with reference to the choice of a profession.

——Prof. Rachel L. Bodley's valedictory address before the graduating class of the Woman's Medical College of Pennsylvania has been published in pamphlet form. We gave a full abstract of this interesting address in a previous number (cur. vol., page 354).

——As there is no opinion so absurd as not to find advocates and defenders, so the opponents of vaccination have found a pleader in Dr. Carl Spinzig, of St. Louis, who sends us a long reprinted article from the St. Louis *Clinical Record*, closing as follows:—

Now, in conclusion, in view of the pathochemical action of variola, and the danger and utter futility of vaccination, above abundantly set forth, must not, then, its claimed "protection" against smallpox be regarded as a vanity, and its continued practice a crime?

——Dr. Charles J. Kenworthy, of Jacksonville, Florida, has written a seventy page pamphlet on the "Climatology of Florida," which is supplemented by a reprint of some articles in the New York *Medical Journal*, on "climate in the prevention and cure of pulmonary consumption, with the special reference to the peninsula of Florida." Much of these writings is strongly polemical in tone, and Dr. Kenworthy, among other difficult points to defend, takes up the positions, that Florida has a dry climate, that it is not a specially malarious State, that phthisis among the native population is comparatively rare, etc. Of course, quite accurate statements on such subjects can only be based upon a considerable number of correct statistics, which, for Florida, are not forthcoming. Those who would like to view the climatic and sanitary advantages of Florida, painted in cheerful colors, will do well to buy the book. (Price twenty-five cents. For sale by Ashmead Brothers, Jacksonville, Florida).

——The question of the water supply of Philadelphia is acutely discussed in a reprinted article by Mr. Reuben Haines, of this city. In connection with his subject he discusses the general desirability of rivers as sources of water supplies, expressing his opinion as follows:—

There is a marked tendency, of latter times, to give up rivers as a source of public water supply, and to seek for it in natural and artificial lakes or large reservoirs in hilly districts. By this plan use is made of the storm waters of the region, and a water is obtained as nearly pure from the clouds, by natural distillation, as can be done on a large scale. The hill country from which the supply is taken must be chiefly in woodland or pasture ground, and should not be in active cultivation. It is also to be noted that sewage contamination is less likely to occur in such a lake than in a river, for it has been observed in many places, and among them, Massachusetts, that the centres of population extend usually along the river courses and seldom settle on the shores of small lakes.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3 20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER-GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE AMERICAN MEDICAL ASSOCIATION.

We devote much of the space in this number to the proceedings of the American Medical Association, at its thirty-second annual session. The interest in the meetings of the Association is increasing with each year of its life, and it has now gained such a position before the profession that its proceedings will command the attention of all members of the medical world.

One pleasant feature is the absence of the barren discussion on personal and ethical points, which some years ago occupied so much time with so little benefit.

The scientific work of the Sections is extensive, and indicates great activity in all branches of professional investigation. The ability in the discussions of mooted points shows how wide awake to the advantages and disadvantages of the various topics of medical study are the physicians of the United States.

The proposition to establish a medical journal to act as the organ of the Association, may expect some comment on the part of editors of existing medical journals. Dr. Warren spoke of a hostility to such a project on their part. We have seen no signs of it. There should be none. A new medical journal is started in the United States about every three weeks, on an average. One more or less should not terrify those at present in the field.

If, however, the gentlemen who advocate this move fancy it an easy matter to establish and conduct successfully a weekly medical journal, they may discover that they are not quite right there.

The decision in reference to the propriety of regular medical teachers signing the diplomas of those who avowedly intend to practice homœopathy, etc., will meet with general approval.

As much cannot be said of the effort—for the time being unsuccessful—of those who wish to prevent the use of copyrighted pharmaceuticals by the profession. A trademark is a guarantee of quality, too generally recognized for the Association to put it aside. Any action in this direction could not be carried out, and would, in fact, be against public policy.

All in all, the meeting of the Association at Richmond was a satisfactory and gratifying one.

AN IMPORTANT QUESTION DECIDED.

Both in England and this country it has long been a disputed point as to whether the lectures delivered by a professor in one of our medical schools or hospital clinics are or are not the private property of the professor. Can a hearer take a verbatim report, publish it, and enjoy the profit of its sale, without the permission of the lecturer? For many reasons most lecturers have opposed such action, and these reasons are valid, so far as the lecturer's personal feelings are concerned. He may express himself without that due care which he would use in writing for the press; the reporter may make serious blunders; the substance of the lecture may be intended for a more complete exposition of the subject in point, etc.

Well conducted journals always ask permission of lecturers to have their lectures reported; and, of course, still less a respectable publisher would not publish the reports of a series of lectures in book form without such consent.

The matter has come before the courts in New York City, through a suit brought by G. P. Putnam's Sons, in which they obtained an injunction from the U. S. Supreme Court restraining the publication of a report in book form of Prof. Darling's lectures on anatomy, it being in conflict with Darling's "Essentials of Anatomy," issued by the Putnams.

Dr. Darling, it appears, gave permission to Dr. Meyer to print some reports of his, Darling's, lecture, but the Court ruled that this did not include the right to *publish* them in book form.

This case seems to rule decidedly, first, that a lecturer can legally prevent any report being printed of his lectures without his permission; secondly, that a permission to print does not include a permission to publish; and thirdly, that the right and title of a lecture rest exclusively with him who delivers it, and do not become vested in those who pay to hear it.

Notes and Comments.

Rupture of Internal Organs without Apparent External Lesion.

We read of two such cases in the reports of the Societé Anatomique (Paris). The first occurred in the service of M. Duplay; the patient had been caught between a wagon and lamp post. There seemed to be no external contusion, but the patient complained of intense pain in the right hypochondrium. At the autopsy a complete rupture of the kidney was found, with a torn condition of the spleen; there was effusion of blood between the layers of the omentum and mesentery.

In the second case, a workman was thrown from a team; his hernia escaped from beneath the truss which maintained it, at the moment of the accident. There was no sign of abdominal contusion, and the symptoms simulated those of strangulated hernia. At the autopsy, a small opening, about the size of a dime, was found in the small intestine; there was effusion of the intestinal contents into the cavity of the pelvis, and generalized peritonitis, but no strangulation of the intestine.

Facts about Pneumonia.

Dr. Edwin M. Snow, in his report for March, as City Registrar of Providence, R. I., discusses the subject of pneumonia, as it appears in that city, and reaches the following conclusions:—

The consideration, thus far, of the subject of *Pneumonia*, justifies the following conclusions; always remembering that the conclusions are for the special latitude and special population of the city of Providence, and that they may, possibly, differ in some respects from those of other latitudes and other populations:—

First—Of the total mortality from known causes the percentage of deaths from pneumonia is no greater and no less than it was twenty-five or even forty years since. There has been no perceptible change in this respect during this time.

Second—The proportional mortality of males from pneumonia is considerably greater than that of females. This conclusion might be modified by a comparison of the mortality, by sex, at different periods of life.

Third—In proportion to the numbers of the living population, there is an excess of mortality from pneumonia among those of American parentage.

Fourth—The mortality from pneumonia seems

to be specially influenced by season and temperature, the number of deaths being least in August, when the temperature is highest; increasing with much uniformity until February, and then decreasing regularly until August. See the table for illustrations.

Fifth—The debility of advanced life and the debility of infancy—age and want of age—seem to be the most important causes of death from pneumonia. Less than one-fourth (23.75) of the living population is under five years and over fifty years of age; but this less than one-fourth of the population furnishes nearly three-fourths (72.66 per cent.) of all the deaths from pneumonia. More than three fourths (76.25 per cent.) of the living population are between five and fifty years of age; but this more than three-fourths of the population furnishes only a little more than one-fourth (27.34 per cent.) of all the deaths from pneumonia.

Treatment of Eczema of the Scalp.

In such cases, accompanied by impetigo, M. Vidal employs, at the St. Louis Hospital (*Progrès Méd*, March 5th), the following treatment:

Lotions with decoction of walnut leaves. Frictions morning and evening with—

℞.	Glycerit. amyli,	℥ j	(30 grams)
	Ol. cadini,	℥ j ⅓.	(6 grams)

Suspend the frictions if they prove too irritating. As general treatment, iodide of iron, the vegetable bitters, and sulphur baths if the constitution be enfeebled, as it is in the generality of such cases. In another very different form of the disease, M. Vidal employed the following:—

℞.	Glycerit. amyli,	℥ j
	Tannin,	℥ ss
	Hydrarg. submuriat.,	gr. xv.

The patient was strong and vigorous, and an eczema of both arms, treated without success by enveloping in rubber bandages, was favorably modified by the above glycerite.

Psylium Seed in Constipation.

We read in *Paris Mèdical* that Mr. Noel Gueneau de Mussy proposes using *Psylium or Sarragota Seed*, besides *white mustard seed*, the use of which is excellent, or *flax seed* in the natural state.

Psylium is a species of plantain, commonly called *Fleawort*, because of the appearance of its seeds, which are quite small, and very mucilaginous. A tablespoonful in half a glass of water is taken before dinner. He says that with a number of persons this method has proven as successful as with the Spanish lady from whom he obtained it. In other cases, however, he was obliged to alternate with more powerful laxatives, such as aloes or rhubarb, so as to keep up the effects. It is probable that psylium seed, like others of its kind, is not persistent in its effects, although in a number of cases it seems to have been so.

Pilocarpin in Scarlatinal Nephritis.

Dr. Seemann gives the following indications for the use of pilocarpin in certain cases of nephritis:—

1. Muriate of pilocarpin is useful in cases of scarlatinal nephritis, and may often save life when other remedies fail; but it must not be resorted to except in very serious cases. 2. When, after its successful administration, the œdema begins to lessen, cure should be left to nature and to other remedies, because renewed doses of pilocarpin may cause too rapid absorption of the transudation, and may thus lead to uræmia. 3. After each dose of pilocarpin, the state of the respiratory organs must be carefully watched; if the bronchial mucus be not satisfactorily expectorated, or if the slightest indication of pneumonia show itself, further doses of the drug must not be given.

Concentrated Solution of Quinine.

A formula for a concentrated solution of quinine is given by Mr. S. W. Reynolds, in the *American Journal of Pharmacy*, April, 1881:—

He adds, that he has no difficulty in keeping any required length of time, and there is no crystallization except in very cold weather, and then it is redissolved very readily by warming.

His formula is as follows:—

℞.	Quiniæ sulphat.,		grs. 480
	Acid. sulphur. dil.,		f. ℥ vj to f. ℥ j
	Glycerinæ,		f. ℥ vj
	Aquæ destil.,	ad	f. ℥ vj.

Misce sec. art. and filter.

Prepare it without heating, and find the f. ℥ vj of dilute acid sufficient in warm weather, but in winter the larger quantity is required, to maintain the solution. This solution contains exactly ten grains in each f. ℥ j.

Death by Pulmonary Embolus in Phthisis.

M. Dugnet presented at a recent meeting of the Societé Med. des Hôpitaux (Paris), the lungs of a tuberculous subject, who died suddenly, through pulmonary embolus. Both lungs were

tuberculous, except the inferior lobe of the left lung, which was obstructed by an embolus plugging up the bronchial tube, and which originated in the right femoral vein, although there was no phlegmasia alba dolens of this limb during life. In the discussion which followed, it was admitted that clots might form in the veins in cachectic conditions, without enough pain or œdema to attract the physicians' attention.

But there may be old thrombi in existence, and the collateral circulation is sufficient to efface the œdema without obviating the danger of a migratory clot.

Eczema from Chloral.

At a medical meeting in Paris, some months back, Dr. Brochin, in speaking of the inconveniences of chloral, related the case of a young, strumous girl, subject to eczema of the lips, who, on two separate occasions, found this affection to reappear immediately on taking a draught and an injection of chloral, and that with such intensity that the mouth and the tongue became involved. The diagnosis of buccal eczema was confirmed by M. Bazin. In the discussion which followed his remarks, others stated that they had frequently observed an erysipelatous-looking eruption on the face, of a painless character, following the administration of chloral in large doses, and disappearing when the drug was suspended.

Elixir of Salicylic Acid.

At one of the recent meetings of the Pharmaceutical Society of this city (*American Journal of Pharmacy*, April, 1881), a formula for *elixir of salicylic acid* was asked for, and Dr. Wolff furnished the following:—

Dissolve salicylic acid, ℥j, in alcohol, f. ℥ vj, and add simple elixir (or elixir curacoa), q.s., f. ℥ vj. The dose is a tablespoonful, containing five grains of salicylic acid, the taste of which is well masked. The elixir should not be given with water. The additional amount of alcohol in this preparation is not contraindicated, but seems to overcome the tendency of the salicylic acid to act as a cardiac depressor. In variola this elixir has been used with good results.

Impairment of Sight from Tobacco.

In the last volume of the *St. Thomas Hospital Reports*, Mr. Nettleship gives some interesting notes on the diagnosis of tobacco noctylopia, and draws attention to the fact that in this affection the central region of the visual field is first affected, and remains throughout the seat of the greatest relative defect, while the periphery of the field remains of the full size. The patients have no difficulty in walking about, but when reading they very often move a printed book about as if trying to discover some position in which it could be better seen. They generally see better first thing in the morning, again towards evening, and best on dull days.

Correspondence.

A Severe Case of Double Quotidian Hemorrhagic Fever.

Ed. Med. and Surg. Reporter:—

Was called, March 8th, 1875, 5 A.M., to consult with Dr. Farrer, seven miles in the country. The history of the case, from my note book, is the following: Mrs. C. H. had, in the evening of March 6th, a slight chill, followed by fever and thirst. During the night she took Smith's Tonic. March 7th, early in the morning, her menses came on; soon after she vomited profusely, clear blood, bled also from the nose, and passed half a chamber full of pure blood, according to her husband's statement. Dr. Farrer, an old physician, was sent for, who gave her the following, viz.:—

℞.	Quiniæ sulph.,	gr. ij	
	Elix. vitriol,	gtt. v	
	Tinct. ergotæ,	gtt. x	
	Water,	℥j.	M.

Such a dose every two hours. This was preceded by a full dose of castor oil and turpentine; besides, she took five grains tartaric acid in one-third of a cup of strong infusion of cinnamon and cloves. At six P.M., of same day, another alarming hemorrhage from the stomach, nose and bowels, occurred, which nearly terminated her life. The Doctor was again sent for; but the hemorrhage nearly ceased when he arrived. He left her six powders, composed of one grain of opium and one grain of ipecac, each, to be given every three hours, and the other medicine continued, having given an unfavorable prognosis, in case the hemorrhage should recur.

March 8th. Early in the morning she had another alarming hemorrhage, and when it ceased, they all thought she was dying. The Doctor was sent for, and another messenger came for me. I found her in the following condition: Her face was blanched and white as a sheet, eyes sunken, voice whispering, pulse scarcely perceptible, respiration thirty per minute, and the extremities cold and covered with clammy perspiration. We retired into an adjoining room; where the good old Doctor objected to any further treatment as useless, she being already in *articulo mortis*. I insisted on doing something for her, and prepared, contrary to his wishes, the following, viz.:—

℞.	Quiniæ sulph.,	gr. v	
	Calomel,	gr. ss.	M.

One such dose to be given every hour, till five P.M.,

if alive, and then every two hours. I gave her also, strychnia sulph., one-quarter of a grain, morphia sulph., one-third of a grain, persulphate of iron, five grains at a dose, and then left her six powders of morphia sulph., one-third of a grain, ipecac., one grain, persulphate of iron, five grains each; one to be taken every three hours, till three powders are taken; further, to take freely the white of an egg, beaten with a little water and alternated with skimmed milk. This treatment was faithfully carried out, when, about five and a half P.M., instead of another attack, she fell into a tranquil sleep, which she enjoyed for three hours and awoke refreshed.

March 9th. Her husband brought me the good news that his wife is better, and requested me to see her again, as Dr. Farrer refused to consult with a doctor using such heroic and barbarous treatment. (Saying that the strychnia alone was sufficient to kill a hog). At my second visit, a pale, but cheerful and friendly face met my eyes, her cool and weak hands grasped my hand, and she exclaimed, God bless you, my dear Doctor, with tears rolling down her cheeks. She took all the quinine powders, twelve in all, which affected her hearing slightly; but the first powder she thought brought life into her, for it went like lightning through her body, and made a peculiar feeling. Of the other powders she took only four. Further, she used the whites of sixteen eggs, and one quart of skimmed milk, during these twenty-four hours. Presently she received the following:—

℞.	Chinin. sulph.,	gr. l	
	Acid sulph. arom.,	ʒ iss	
	Ext. caryophylli,	ʒ v	
	Tinct. cinnamomi,	ʒ j	
	Ext. hydrastis canad.,	f. ʒ ij	
	Syrup sarsaparillæ,	ʒ iss.	M.

Sig.—One teaspoonful every three hours.

Also,

℞.	Tinct. ferri muriat.,	ʒ j	
	Acid. nitro-muriat.,	ʒ ss	
	Strychniæ sulph.,	gr. j	
	Tinct. calami,	ʒ j	
	Glycerin pur.,	ʒ ss.	M.

Sig.—Three times a day; one teaspoonful a quarter of an hour after meals, in water.

These two prescriptions were once repeated, and in fourteen days from my last visit she came with her husband to my office, to settle the bill.

About eight months afterward this lady had another attack; sent again for her physician, Dr. Farrer, who promised to cure her with the same remedies I had previously given; but she died within thirty-six hours, from hemorrhage, which this time came from stomach and bowels only. One thing I shall mention with this case, that is the large dose of strychnia she received, producing a powerful shock to the nervous system, and at the same time keeping up a prolonged stimulant and tonic effect on the same. I had, time and again, flattering results from one quarter of a grain of strychnia sulph., sixteen grains of quiniæ sulph., and one-third of a grain of morphia sulph., given at a dose, in congestive chills, and then pushing the quinine and stimulants hourly, till out of danger. Only but two weeks ago I saved a poor widow from a too early grave by such a powerful dose, which acted magically. Her disease was cerebro-spinal meningitis, of a severe character. Her treatment, after this dose, consisted of a compound mixture of chloroform, ch. p., tinct. gelsemini, ergotin, ext. cannabis ind., fl. ext. belladonna and glycerine, in full doses every three hours; also a nightly dose of sixteen grains of sulph. quinine, and one-eighth of a grain of strychnia sulph., with hot applications to the nucha and upper part of the spine, frequently repeated. The other cases, not so severe, ended also in recovery, under exactly the same principle. J. Pirnat, M.D.

Evansville, Ind.

Mechanical Uterine Support.

Ed. Med. and Surg. Reporter:—

I was called, May 24th, 1880, to see Mrs. E., aged thirty-three, mother of five children; has had two miscarriages; had suffered five years with increasing discomfort until she was bed-ridden with five weeks' hemorrhage from womb. She was greatly reduced, anæmic, with some malarial poisoning; but, to be brief, for I desire to call the attention of the profession to two kinds of help, in mechanical therapeutics in uterine diseases and displacements, in this case I found the side of uterus just within vulva, the os against meatus, the fundus against rectum, preventing the passage of urine or catheter until pushed up. There was erosion of os, great enlargement and induration, also endocervicitis. The vaginal walls were so much weakened and dilated that for some time I was puzzled to keep the uterus in position; large-sized cotton pads would be slided right out as soon as she was lifted to the mug. I at last introduced a pad, and then packed the vagina with cotton wool, moistened with tannated glycerine, placing a large pad on external labia, and confined by a bandage fastened to the belt around waist. After ten days the vagina had so far recovered that the cotton pad was retained as a pessary.

Seeing the advertisement of S. S. Staufer, in the Reporter, I ordered for this case a high-priced instrument, but asking him to use his judgment; he sent an "Economy" belt, with deep E. O. cup, two inch diameter, for $2.50 less than the amount sent. June 25th I fitted on this instrument; the lady resumed the care of her household immediately. On the 9th of July I met her at a camp ground, she having walked there, a distance of two miles. She was the picture of health. Two weeks ago she assured me that she was and had been in as perfect health as when a girl. To the os and cervix I applied, with a camel's hair pencil, tincture of iodine and carbolic acid. There was no hemorrhage after the first twenty-four hours. As soon as the cotton pad could be retained by the vaginal walls, the pad was covered with glycerite carbol., five per cent. carbolic acid.

This case has been of great value to me, and I am sure that I am largely indebted to the use of Staufer's hard-rubber uterine supporter. In fact, all of his instruments that I have seen are admirably adapted to secure success in their use,

and I most cheerfully recommend them to the patronage of the profession.

J. C. Aubrey, M.D.

Culverton, Ga., April 4th, 1881.

Vaccination and Measles.

Ed. Med. and Surg. Reporter:—

Some two months ago we had somewhat of a smallpox scare in this community, and, consequently, I was called upon to vaccinate a great many persons. About two weeks after I commenced vaccinating an epidemic of measles started in the town, and very rapidly spread through the city and adjoining country, assuming quite a severe type. In fact, so severe, that several cases died, and some of the physicians reported the epidemic as one of "*black measles.*" I observed that all those cases that came down with the measles about the time that their arm was getting sore or was still sore, from the effects of the vaccination, had a very mild attack, and recovered quickly, without any complications whatever supervening, many of them not being confined to the bed at any time during the sickness, and if at all, not more than one day. This held true with adults as well as with children. And further, I observed that where I vaccinated after recovery from the measles, the results were very unsatisfactory. I remember one instance in particular, where I vaccinated five children in one family, some ten days after recovery from measles, and not one worked. Thirteen other children who had not had the disease during this epidemic, were vaccinated the same day, from the same virus, and in the same manner, without a failure. If any practitioner has an epidemic of measles on hand, or should chance to have in the future, I would like to have them investigate this subject further and report the result.

Parkersburg, Iowa. A. O. Strout, M.D.

News and Miscellany.

The Sanitary Council of the Mississippi Valley.

The Council met at Evansville, Indiana, in the third week of April. A committee of eleven members, Dr. J. D. Plunkett, of Tennessee, Chairman, was appointed to submit propositions covering the work of the Council. They reported April 21. They spoke in favor of representatives of the National Board of Health residing at quarantine stations on the Mississippi river, and also one at New Orleans, with the privilege of searching the records of the State Boards of Health and attending their meetings. The difficulty with the Louisiana State Board of Health was deplored, and the action of the State Board condemned. The following resolutions were adopted:—

Resolved, That the inspection service of river and rail transportation by the National Board of Health is hereby desired, and its reëstablishment for the ensuing season is urged, on behalf of representatives in this Council; that certificates and bills of health issued by said inspection service shall be accepted as *prima facie* evidence of the sanitary state of vessels and trains presenting the same.

Resolved, That this Council, being firmly convinced that the safety of New Orleans, as well as the valley, lies in the rigid exclusion of infected ships from the Lower Mississippi, strenuously urge upon the State Board of Louisiana, a modification of section 6, of the rules and regulations for the government of quarantine officers and stations, etc., so as to read: Section 6. All vessels from ports at which yellow fever is prevailing, or from ports where contagious or infectious diseases are reported to exist, shall be inspected at Eadsport. If any such are found to be infected, or to furnish reasonable ground for suspicions of infection, such vessels shall not be allowed to pass Eadsport, northwise, except upon the presentation of a certificate from the Inspector of the National Board of Health, at Ship Island Quarantine Station, setting forth that the vessel has been subjected to proper treatment and is free from the liability of conveying the contagion.

Resolved, That in the judgment of this Council the quarantine of vessels and freight should consist of purification of the vessel and its contents, which should then be returned to commerce as speedily as practicable.

3. The means of informing the Board of Health in the Valley of apprehended danger.

Resolved, That this Council condemns all methods of suppression and secrecy with reference to information of contagious or infectious diseases; therefore discountenances the use of cipher telegrams; but in the event of danger from such diseases at any point in the Mississippi Valley, it is the duty of the executive officer of the health organization of such place to fully and promptly advise the proper authorities at all threatened points.

Dr. J. J. Speed, of Louisville, was elected President, and Dr. Johnson, of Mississippi, Vice President, for the ensuing year.

Smallpox in London.

Smallpox is epidemic in London. It was officially announced that during the month of April more than 1500 cases of smallpox had been refused admission to the hospitals, because they were full. There were then 1014 cases of smallpox in the London hospitals, and only one bed available. The deaths of 297 persons from smallpox, in their own homes, were reported since the outbreak of the epidemic, which, moreover, had much increased in violence.

Filthy Streets and Filth Diseases.

From New York City and Chicago come outcries against the filthy condition of the streets and the disastrous consequences on the health of the inhabitants. The New York mortality bills are far higher than usual at this season of the year, and even true typhus fever has broken out in some localities. In Chicago matters are even worse. In the first week in May, the Chicago *Times* stated:—

"The death-rate in Chicago is greater now

that it has been at any time for many years past. The health of the city is worse than it has been for many years. The mortality among children is simply frightful, while grown people are suffering and dying from lung and bowel complaints in every section of the city. Our drinking water is unfit for use; it is breeding disease that may not develop in a day, or a week, or a month, but which will surely develop in time. Our streets and alleys are reeking with filth. Our sewerage system is incomplete and imperfect."

It was even said that twenty per cent. of the population of the city were more or less affected by these causes.

Act Relating to Color-Blindness.

The following Act has been passed by the Legislature of Massachusetts and approved by the Governor:—

SECTION 1. No railroad company shall employ or keep in its employment any person in a position which requires him to distinguish form or color signals, unless such person, within two years next preceding, has been examined for color-blindness or other defective sight, by some competent person, employed and paid by the railroad company, and has received a certificate that he is not disqualified for such position by color-blindness or other defective sight. Every railroad company shall require such employé to be reëxamined at least once within every two years, at the expense of the railroad company.

SEC. 2. A railroad company shall be liable to a fine of one hundred dollars for each violation of the preceding section.

SEC. 3. This Act shall take effect on the first day of July next.

Association of Medical Officers of American Institutions for Idiotic and Feeble-Minded Persons.

The sixth annual session will be held at the Kentucky Institution for Feeble Minded Children (Dr. John Q. A. Stewart's), commencing Tuesday, May 17th, 1881, at 8 o'clock, P.M.

The following papers will be presented and discussed:—

1 "Some of the Abnormal Conditions of Idiocy, and the Method of Obviating Them." Dr. H. B. Wilbur, Syracuse, N. Y.

2. "The Epileptic Change: and its appearance in Idiocy." Dr. I. N. Kerlin, Elwyn, Pa.

3. "The Rate of Growth of Idiotic Children, Compared with the Normal Standard." Dr. Geo. G. Tarbell, Boston, Mass.

By resolutions of previous sessions, the following reports will be made at Frankfort:—

"On Bibliography of Idiocy, etc.," Dr. H. B. Wilbur, chairman (minutes, p. 43).

"On Statistical Records," Dr. G. A. Doren, chairman (minutes, p. 45, p. 113).

Dr. Tarbell, of this Committee, will report a special paper on the "Defects of Statistical Inquiry."

"On Causation of Idiocy, etc.;" Superintendents reporting illustrations from cases received into Institutions for past year (minutes, p. 43).

"On Status of the Work before the people and legislatures of the various States" (minutes, p. 43).

"On Development and Progress of the Institutions represented."

"Improvements in School Training and Hospital Care introduced during the past year."

"Clinical reports of special cases" (minutes, p. 41).

By resolution of 1880 (minutes, p. 114).

1. That in the State reports for 1881, statistics of epilepsy shall be furnished, *e. g.*, the number of cases in the institutions who are, or who have been, epileptic; also the number of applications for admission declined during the year, because of the complication of epilepsy.

2. That the members of the Association report, for 1881, the progress of pupils in the industrial departments of the same institutions.

It is especially requested that members report at least as early as 5.30 P.M. on the 17th instant, so that the first meeting may be held at 8 P.M.

ISAAC N. KERLIN,
Elwyn, Pa., May 2d, 1881. *Secretary.*

The Kansas Temperance Act.

Some objections having been made to our statement of the effect of the Kansas prohibitory law (see REPORTER, cur. vol., p. 453), we submitted a copy of the Act itself to two competent lawyers of this city, and both pronounced, unhesitatingly, that the statement we made is borne out by the wording of the Act.

Items.

—Smallpox appears to be making the tour of the world, coming on vessels sailing westward across the Atlantic, and eastward, on ships crossing the Pacific.

—Rhode Island physicians residing near the Connecticut line are denouncing a new law of the latter State which requires a heavy license of non-resident physicians practicing therein.

—The widow of the late Dr. S. B. Wylie Mitchell, a United States Navy Surgeon, has presented that gentleman's choice collection of works on Heraldry, Coats of Arms, etc., to the Historical Society of Pennsylvania.

—The Northern Medical Society, of Philadelphia, elected two lady physicians to membership at their last meeting. This is the first society to admit them in Philadelphia. They were Dr. Hannah Croasdale and Dr. Ida Richardson.

—The York Pennsylvania Hospital and Dispensary was opened, with appropriate ceremonies, April 28th. Dr. W. S. Roland delivered an address, followed by Dr. John L. Atlee, of Lancaster, and others. The Legislature has appropriated $7000 in aid of the Institution.

—The death is announced of M. Ramel, whose name will ever be associated with the beneficent Eucalyptus globulus, or fever destroying blue gum tree of Australia, introduced mainly by his means into Algeria and Europe, and about which there has been considerable interest manifested by American sanitarians.

—A number of physicians have permanently organized the West Philadelphia Medical So-

ciety. Officers for this year have been elected and a Constitution adopted, which says that the society's objects are to advance the cause of medical science and to promote original investigation on the part of its members.

—Advices from Bagdad state that the ravages of the plague are terrible, though not extending beyond the sanitary cordon. Four thousand inhabitants quitted Nedjed and encamped in salubrious localities. Nedjed and Dijukwa were burned on the 8th inst. The disease becomes very violent, the afflicted dying in ten hours after being attacked.

OBITUARY NOTICE.

Death of Mrs. S. W. Butler.

We announce with regret the death of Mrs. Annie H. Butler, widow of the late S. W. Butler. M.D., the former editor and proprietor of the MEDICAL AND SURGICAL REPORTER. Her death took place from cardiac disease and complications, at Asbury Park, New Jersey, May 9th, 1881. Her loss will be felt by a wide circle of friends in this city and in Burlington, New Jersey, her former home. To her unfaltering aid and willing sacrifices the successful existence of this journal during its early and struggling years was in no small measure due. As a devoted wife, a tender mother, and an earnest Christian woman, her memory will long be cherished by those she has left behind.

QUERIES AND REPLIES.

Ethical Queries.

1st. Dr. A. is a graduate of a regular school, and is the only physician in a rural village. Dr. B. locates in the same town with A. and is a stranger; claims to be a "regular," but never called on Dr. A.; not ever having met A. (even to speak to him), ignores him entirely. Is this contrary to the code? Should A. call on B. first?

Ans.—Courtesy requires B. to call on A. first, but the code does not demand it.

2d. A. and B. are physicians of neighboring villages. A. was called to see a case on Saturday. On Sunday, his second visit, he learned that the young man became alarmed and sent for Dr. B., early that morning, but now was sorry that he had sent for him, as he was doing well, and if B. did come, would not employ him. A., on his way home, met Dr. B. and apprised him of the facts; however, B. visited the patient and gave advice. Did B. violate the code? T. M. T.

Iowa.

Ans.—Dr. B. should not have called after Dr. A's. statement to him.

MR. EDITOR:—In a recent case of asphyxia, from hanging, the patient was cut down before death, but remained insensible, breathing at irregular intervals, three or four times a minute. The insensibility continued twelve hours, at the end of which time he died.

I ask in regard to the propriety of injecting one-tenth of a grain of atropia every ten minutes, in such a case.

In a case of strangulation, the nervous and muscular ystems are very much depressed, by the circulation of dark colored blood. The question naturally arises, then, would the hypodermic injection of atropia hasten death or prolong life? Would such a course of treatment be rational? W. H. M.

Indiana.

MR. EDITOR:—Dr. W. H. K., of Ohio will find a paper on Soluble Compressed Pellets for Hypodermic Use, in *Medical Times*, January 1st, 1881.

In answer to C. C. S. of Ala., p. 448, would refer you to an admirable reprint of a paper on Abuses of Medical Charities, by Roswell Park, M D., 1558 Wabash av., Chicago, Ill. I am sure Dr. Park will take pleasure in sending a copy to C. C. S., of Ala. H. A. W.

MR. EDITOR:—In answer to W. H. K., of Ohio, vol. xliv, morphine and atropia salts dissolved in water 2 parts, glycerine 1 part, will keep without changing. I have used, for many years, the following solution of morphine for hypodermic use, and have never seen it cause any irritation where injected:—

℞.	Morph. sulph.,	grs.xxiv
	Glycerine,	ʒiiss.
	Aquæ.	ʒvss. M.

Grs. iii to ʒj—Hypodermic use. A. E. SPOHN.

Corpus Christi, Texas, April 22, 1881.

L. N. D., of Ind., writes: W. R., aged 25 years, never perspired sensibly in his life; never had but one rudimentary tooth, which he soon lost; and little or no hair on his head. Is a farm laborer, and in hot weather keeps his clothes constantly saturated with ice water. Has always enjoyed reasonably good health. Are there any such cases on record? If so, what is the anatomical condition of the skin.

Dr. W. W. S., of Ohio.—Liquor carbonis detergens is an English proprietary, antiseptic preparation, the exact composition of which is not published.

Dr. P. H. J., of N. Y.—On Bright's disease, the latest (and the best) book is that by Dr. Tyson, just published in this city.

MARRIAGES.

KYLE—McCULLEY.—By Rev. Thos. S. Park, April 12th, 1881, at the residence of the bride's parents, near Smithfield, Dr. Warrick P. Kyle and Miss Emma J., daughter of Mr. John V. McCulley, the former of Hopedale, the latter near Smithfield, Ohio.

PRICE—ALDEN.—On Wednesday, April 20th, 1881, at St. Andrew's Church, 127th st. and 4th av., by the Rev. Francis Lobdell, Dr. Sherman B. Price and Miss Jannat Hills Alden, daughter of James M. Alden, both of New York.

ROBBINS—PIKE.—April 30th, at Pomfret, Conn., by the Rev. Ebenezer Thompson, James Henry Robbins, M.D., of Hingham, Mass., to Mary Caroline Pike, of Robbinston, Maine.

DEATHS.

ABBOTT.—On the 25th ult., Emma C. Abbott, wife of Dr. Benjamin T. Abbott, of Tuckahoe, New Jersey.

DAVIES.—On April 14th, Near Golden Lake, Ark., of pneumonia, Dr. J. F. Davies, aged 56 years.

GOLDMARK.—In New York, on Monday, April 18th, Dr. Joseph Goldmark, in the 61st year of his age.

HOLT.—At Montgomery, Alabama, Dr. W. J. Holt.

HUBBARD.—In Wauconda, Lake Co., Ill., January 25th, 1881, of cancer, Phebe N., wife of J. A. Hubbard, M.D., aged 42 years.

KRIDER.—Near Logan, Ohio, April 16th, Dr. S. C. Krider, of typhoid pneumonia, aged 65 years. He was one of the oldest physicians of Hocking Co.

TREVER.—April 21st at Quincy, Ill., Dr. Hugh Trever, of St. Joseph, Mo., in his 76th year. He had practiced in St. Joseph for nearly 40 years.

WARD.—April 22d, at Monticello, Ill., of heart disease, Dr. J. R. Ward, in the 70th year of his age.

ANTIPODAL HONORS.

"At the World's Fair at Melbourne, Australia,

Messrs. W. H. Schieffelin & Co.,

of this City, received the **first award of merit** for their exhibit of

PHARMACEUTICAL PREPARATIONS,

including fluid extracts, etc., and also for their soluble pills and granules. This recognition from the Antipodes of the excellence of their preparations—which has long been conceded at home—must be exceedingly gratifying to the **Messrs. Schieffelin,** and is a matter of just pride to patriotic Americans generally."

BAKER'S EMULSION COD LIVER OIL WITH HYPOPHOSPHITES OF LIME AND SODA

Each table-spoonful contains five grains of the Hypophosphites.

AGENTS FOR

BARNETT'S PILL SUPPOSITORIES

A Safe, Convenient and Thorough Remedy.

JOHN C. BAKER & CO., PHILA.

1180eow-tf

A PERFECT AND POTENT PREPARATION.

Approved and recommended by the profession wherever introduced.

CONTAINS **50 per cent.**

BAKER'S PURE NORWEGIAN COD-LIVER OIL.

16 oz. bottles.

Sold by all druggists.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

A CASE OF PROLONGED GESTATION AND UNUSUAL LABOR.

BY MARY HARRIS THOMPSON, M.D.,

Head Physician and Surgeon to the Chicago Hospital for Women and Children, Vice President of the Chicago Medical Society.

Read before the Chicago Medical Society.

On July 4th, 1876, I was called to visit a young Swedish woman, who was convalescing after a severe labor, which had occurred about two months before. Her friends stated that she had had "spelis" for some five weeks previously; that she would have six or seven in a day; *occasionally* there would be *less*, but they were now generally increasing in frequency and violence, and that "each spell" was liable to last longer.

The patient was of medium height and size, had fair hair, light complexion, blue eyes and decaying teeth. She had lived in America some years, and spoke English well. She had at this time a nervous appearance and would start as if afraid of any movement made in the room. Her friends said, if a stranger should enter unannounced, she would fall to the floor in a "fit." She sat up but a small portion of each day.

During this visit, physical examination revealed no malady of heart, lungs, brain or spinal cord, unless the convulsions were indications of the latter. Other organs were healthy, so far as could be learned, until the pelvis was reached, when *here seemed* to be the whole cause; though we feared not, when chance compelled us to witness the first convulsion; it was so epileptoid in character.

A vaginal examination discovered a large amount of cicatricial tissue in that canal; the larger part of which was in two long ridges extending from the orifice of the vagina, on either side, to the cervix uteri, where they were lost on the lateral walls of that organ. Shorter ridges of the same cicatricial tissue radiated from points along the whole line of the longer ones, but were larger and more numerous near the cervix. A considerable stenosis was already the result, though these cicatrices were not yet healed. The cervix lay spread open like a book, in the vagina, from one long laceration in the median line anteriorly, extending from the middle of the anterior lip very nearly to the junction of the body and neck. Another laceration existed at the junction of the two lips on the right side, but was only about half an inch in length, and apparently healing. The walls of the cervix were thick, patulous, and denuded of their epithelial surfaces, both internally and externally, on the lower portion, as also was the os. The edges of the wounds were granulating. The ridges in the vagina looked as though folds of the mucous membrane had been taken up, with an effort to remove portions in these lines.

Her history was taken only from the time of marriage, or rather from the birth of the first child, which occurred about four years previous to this date. She was then twelve hours in labor, was attended by a midwife, who used the forceps, but for *what reason* she would not state. She began using them at two o'clock in the morning, and was three hours in terminating the labor. During these three hours she removed and replaced the instruments many times, a sister, who was present, says "twenty, at the least." Her gestation had been natural, except

some pain, at the end of each month; and during the last one there was some pain almost the entire time. She had never been well since this labor.

Her second delivery occurred about two years before my being called in, and was quite natural; she was in labor but two hours and no forceps were used.

The third and last child was born about two *months* previous to this first visit. This labor "was long and tedious." She was attended by three doctors, who were a long time in using the forceps, the use of which was preceded by a knife, used probably upon the os uteri, preparatory to the use of the forceps.

I learned at this visit that she began having convulsions during the first month of this last pregnancy, and that they continued until she visited the dispensary of the Chicago Hospital for Women and Children, on one of my days, when she was five months advanced in gestation; that a specimen of the renal secretion had been obtained, and was being tested; also, that she had received one prescription, when she fell in a convulsion. In consequence of this accident, her friends hurried her home before another convulsion should come on. Hence she was not treated for albuminuria, though it was found to exist. Her address had not been taken, and I had never seen her since her visit at the dispensary until called to her home, some six months afterward. She assured me that she had taken the medicine regularly during the last four months of pregnancy, and had had no convulsions until three weeks after this last severe labor. She did have "stiffening" of the limbs and of one side, and would feel as though a convulsion was coming on. The prescription was the bromide of potassium in ten grain doses, ordered to be taken three times daily, when she felt nervous. At this visit the urine was examined and very little albumen was found, so little that nothing was done for it.

The treatment was the muriated tincture of iron and the bromide of potassium or ammonia. The local treatment was the vaginal douche and topical applications of a strong solution of nitrate of silver, made every fifth day. The convulsions grew less in frequency, and lighter in form, simultaneously with the healing of the parts, and disappeared wholly when this malady was removed.

I should have stated that, at the beginning of treatment, the body of the womb retained its normal relative position to the neck, but as the swelling of the cervix disappeared, it fell backward to the opposite side of the greater laceration, so that its canal made a right angle with that of the neck. This I could not correct. After many months the parts were healed and she was dismissed as well. About three months after this I was recalled, with the news that she was again having convulsions, and that she thought she had had a miscarriage of a few weeks. The only way this could be substantiated was by the condition of the parts. The body and neck of the womb were large and patulous, the internal os more open, and a sanguineous leucorrhœa established. The shorter laceration had nearly disappeared by cicatrization, the os was becoming eroded, and the edges of the larger laceration were again thickened and granulated, though there was no disposition shown to close up, like the shorter one. Once more we labored to stimulate the parts to heal. When healed, the question arose as to *how* to help the woman keep well, that she might not be a perpetual patient. We had heard of Dr. Emmet's operations upon these rents of the cervix, but I had not chanced to read any article upon the subject, though Dr. Emmet had already published one paper in the *American Obstetrical Journal*. I thought out my own plan of operating, but did not succeed in securing the best result.

The first operation was late in November, 1877. The result was a thin bridge of superficial muscular fibres, with a continuation of the mucous membrane covering the cervix, with a fistula at the bottom of the wound, or top of the cervix, and an open external os. As the denuding was not extended to the full edge of the os sufficiently, and I dared not denude the wound at the bottom (as the rent had extended so high into the supra vaginal portion of the cervix), we feared entering the peritoneal cavity. In consequence of this imperfect condition, there was a constant tendency to ulceration of the cervix and os (internally as well as externally), and as frequently a return of convulsions.

She consented to a second operation, which was made March 20th, 1878, with a much better, though not what I should now consider a *perfect* result. It kept the walls of the cervix together, also the body in its natural position. There was no longer any tendency to excoriation of the parts. It is now nearly three years since this patient had a convulsion.

Question. Had insanity occurred instead of convulsions, and the patient been placed in an insane asylum without the recognition of the cause, and had no treatment been given, where

would insanity have ceased? Or, if the disease after these five years had been learned and cured, would the effect on the brain cease also?

But questions in physiology and pathology other than these can be asked; for the patient has passed through another gestation and labor, and it is our firm conviction that her pregnancy lasted ten and one half months, if not more. May 20th she came to my office, saying she had not menstruated since January 10th. I then thought it was occasioned by pregnancy, but could not declare this to be the case positively. She came again the 28th, when I felt more certain about it. July 27th, she appeared again, when, I find by my notes, my conviction was that she was *six*, *almost seven*, months pregnant. This was not only shown by the size of the body of the womb and the length of the cervix, but it corresponded to her time of "quickening," or when she felt life. Her labor occurred November 26th, 1880. Nine weeks before this date she called me, thinking herself in labor. I found the os uteri sufficiently open to admit the tips of two fingers, but not thinned away much. Its whole circumference seemed full of cicatricial tissue, in the form of little nodules, except at the point operated upon. We watched the pains, which came on every fifteen minutes, but which had no effect upon the lower segment of the wound. She had constant pains during the remainder of her pregnancy, which were really always worse at night. Some days they would recur every hour or so; at other times every fifteen minutes, even every *five* minutes. I was called several times during October and the early part of November. October 9th, the membranes ruptured, the os thinned away a little, and pains came on every five minutes, but there was no effect yet upon the os, more than a slight thinning and the least perceptible dilatation—when the patient grew more comfortable and "slept better that night than for a long time." I advised with Prof. Byford, who said, "leave it to nature." Soon after this I asked Dr. Bartlett to see the patient with me, which I think he did late in October. He, too, thought it "better not to induce labor." I was called again and again, to attend the woman in labor, but always with the same result—no dilatation, or even pressure upon the lower segment of the uterus synchronously with the pain.

She had some nervous symptoms, such as headache, during the last month of pregnancy, and some albuminuria, which was always relieved by dry cups.

During the latter part of November I was called east, and advised her to go to Dr. Bartlett if her labor should come on during my absence. The history of this labor is given by Dr. Bartlett.

Was this delay of labor caused by a loss of continuity in the muscular tissue at the point of the fistula, at the bottom of the wound? Dr. R. G. Bogue, who was present, said "the fistula dilated as the os did, until after he cut the bridge made by the operating."

Another question arises as to how these operations will affect after labors? Has any one had the experience in obstetrics of finding a cervix that has been rent and mended with silver wire by the surgeon?

Dr. Bartlett reports that the case continued under his observation, as reported, until November 26th, the patient having pains with considerable regularity, night and day, about every fifteen minutes, excepting that every third night she, apparently from sheer exhaustion, sank into sleep. The temperature was normal, the pulse about 100°, the skin and tongue natural. The bowels were regular, the appetite very defective. The morale of the patient was remarkably good. She was patient, courageous and even cheerful.

About noon on the 26th the severity and frequency of the pains increased so decidedly that Dr. Bartlett determined to consider that labor had set in, and to act in accordance with that consideration. The os uteri remained exactly as it has been described above, open to the extent of admitting the tips of two fingers, and in no wise yielding to the increased force and frequency of the pains.

Toward evening, Dr. Bartlett directed that a gallon of hot water be played upon the mouth of the womb for one quarter of each hour. At 11 o'clock, P.M., the os was perceptibly softer, the nodular indurations were less marked, and it was open enough to admit the ends of two fingers. The sinus or opening to which reference has been made as remaining after the operation, and which had always been easily recognizable, was now more distant, more patent, feeling so very like an os in the beginning of labor that it would have been easy to mistake the opening for the mouth of the womb.

Dr. Bartlett invited as consultants in the case two gentlemen to whom he had previously detailed its history, the one of whom favored trusting to nature and time in its management, while the other had expressed an inclination toward active interference: Drs. John S. Clark and R. G. Bogue. Upon consultation, it was agreed that the time had arrived when delivery should

be effected. The pains were frequent and as severe as could be expected in so feeble a patient; the pulse was increasing in frequency. She was complaining of fatigue, and headache was threatening.

It was presently ascertained that the head presented, that it was hydrocephalic, with the sutures quite widely separated, that it was not large, and was not, on account of its size, impeding labor, that it was slightly fluctuating, so that during a pain its coverings became tense, like a bag of water. In view that at several different times during the past seven weeks the patient and attendants had stated that "there had been gushes of water," and seeing that the volume of the uterus had at times seemed less and the outlines of the child more apparent than usual, it was assumed at first, that the membranes had ruptured, and that the examining fingers rested upon the scalp of the fœtus; presently, however, toward one side of the pelvis a sac of water began to form, in the shape of a disk, which soon encroached upon the presenting part of the head, and finally assumed the position and feel of an ordinary bag of water.

It was determined to forward the labor by gently and slowly dilating the os, and this was accomplished by the fingers. Toward four o'clock on the morning of the 27th the pains were losing their force and frequency, the os was dilated to a diameter of two and a quarter inches, with edges about one-fourth of an inch in thickness, was apparently indisposed to dilate further. It was not exactly rigid; it was slightly yielding, and yet not in that state of dilatability which is required for safe delivery. Meanwhile, the powers of the patient were beginning to wane, and as the intensity of the headache became alarming, in view of the history of the patient, the presence of albumen in the urine, and the threatening head symptoms of uræmic character which had occasionally occurred in the past few weeks, while immediate delivery was desirable, it was regarded as impracticable or dangerous with the condition of the os that then obtained. With a hope of improving its state, chloroform was given, to a moderate degree, during pain, for half an hour, but without result. Meanwhile, the condition of the patient grew worse, she was losing hope, her strength was failing, her pulse was 120 to 124. Voluntary efforts during the pains were ceasing, and moanings were taking their place. It may here be stated parenthetically, that during the pains the pulse was 100, while in the interval it was 120 to 128. This peculiarity was explained thus: while pain was in abeyance the pulse was feeble, whereas the stimulus of the pain for a moment increased the power of the heart. This peculiarity of the pulse was regarded as indicating exhaustion. Toward six o'clock the os uteri, yielding, apparently from the approaching exhaustion of the patient, was found somewhat more dilated and softer. Immediate delivery was decided upon. Simpson's forceps were used, some difficulty being experienced in their introduction, because of the high position of the head and the imperfect dilatation of the mouth of the womb. The first blade being in position caused the opposite margin of the os to be drawn over beyond the centre of the presenting convexity of the head, thus embarrassing the introduction of the second blade. The head was finally seized above the superior strait. An examination revealed the os uteri greatly upon the stretch, and it was noted that the fistulous opening was greatly distended, the margin of the cervix formed by the united edges of the laceration being so stretched as to render a new laceration inevitable. It was decided to enlarge the os by incising this tissue with a knife. The head was extracted very slowly and very cautiously; the prolapse of the anterior and posterior walls of the vagina adding emphasis to the suggestion of caution expressed in the condition of the os.

The patient recovered without a single unfavorable symptom. The head of the child was found as described; a spina bifida and a club foot existed; it expired some hours after birth.

Dr. Bartlett says: "Naturally it will be concluded that the prolonged gestation was in part caused by the reunion of the lacerated cervix. In this connection this fact should be mentioned: The pregnancy preceding the last was prolonged, if we may believe the testimony of the patient and her relatives. Not only so, but according to testimony, she fell into labor at the usual period, and was visited by physicians, who gave her assurance of prompt delivery. In lieu of which the pains subsided and did not recur for a month, when, after three days of unavailing pains, she was delivered by the forceps, the knife having been first resorted to, as was believed, for the purpose of enlarging the cervical ring.

By reference to facts given in systematic works on obstetrics, it will be recognized as established that gestation may be prolonged far beyond the usual term. Thus Joulin, who writes at length on this subject, cites cases where pregnancy was extended to *ten* months, to *ten and a half*, to 343 *days*, and even to *one* YEAR.

I would like to bring before this Society, for discussion, the advisability of operating for lacerations of the cervix immediately after labor. The exposure of the patient at this date for an operation, when she is so exhausted, and when the whole physical economy seems to rebel against such an additional ordeal, seems fraught with great danger, too great, unless some severe accident has occurred, such as an extensive laceration of perineum, or other parts, which demands surgical interference, on account of hemorrhage or other danger to life.

All know how the perineum, when lacerated, and when the rent does not pass through the sphincter ani, will heal, if the wound is kept clean and there is a coaptation of its walls. Dr. Emmett says of lacerations which occur in the median line and are confined to the cervix, "these lacerations generally heal rapidly, leaving scarcely a cicatricial line to mark their course." Although the healing of this especial point is contrary to my general experience, I believe that many lacerations of this part are united by first intention, and afterwards are never recognized, but the locality of which is governed in each case much by the position of the patient while in bed. If there is even a small chance for repair, it seems better to wait two or three months than endanger the woman's life by exposing her for operation at a time when a slight chill may result in any or all of the inflammatory maladies of the pelvis that come to the puerperal woman.

It is the obstetrician only who knows how easily these chills are induced at this time.

These operations can be safely performed at any time after the second month subsequent to delivery, as I have recently proved to my own satisfaction; if done with care to both mother and child.

Of these cases, one woman had been *seven weeks* confined; one *nine weeks* and one *seven months*. Two were nursing their children; yet, in neither case was there any inconvenience to mother or infant, other than that the mother was restrained somewhat in regard to exercise, after getting up, the second day after the operation. There was perfect union of the parts in each case.

Recurrent Streams in Syringe Nozzles.

It is by no means a new device to provide urethral syringes with nozzles so perforated that the stream ejected is thrown backward, toward the external meatus, instead of forward. The same plan has been adopted in the manufacture of uterine syringes. The advantages are supposed to be that the discharges are forced toward their exit, without danger of injury to the deeper parts.

CATCHING COLD.

BY DR. CARL SEILER,
Of Philadelphia.

Read before the Philadelphia Laryngological Society.

In the February number of the London *Lancet* (American edition) will be found a short article on the rationale of cold catching, which in a few words says a great deal which it would be well both for the physician and the layman constantly to bear in mind. I shall, with your permission, quote from the article, which I am sorry does not bear the name of the author, and use it as a text for this paper.

I quote: "practically the human organism must be maintained at a temperature equal to 96.5 degrees Fahrenheit, in all climates. The source of this heat is within us, and we wear clothes to minimize the expenditure of this heat by radiation."

About the first part of the quotation I have nothing to say, except that 96.5 is rather a low average normal temperature for the human body, and it is generally estimated to be about 98 degrees Fahrenheit. The second proposition, that the source of heat is within us, requires some explanation. Heat is produced in the animal organism in two ways; first by oxidation of food, and second, by the conversion of muscular movement into heat, according to the now well established law of the correlation of forces. How and where this oxidation of food takes place I will not here enter into, but will state that certain articles of food yield a larger amount of heat than others. Thus animal food, and especially animal fats and oils, produce more heat when introduced into the system than farinaceous food and fruits do. This we find exemplified in contrasting the mode of living of the Esquimaux and other inhabitants of the north with those dwelling in the tropics.

The Esquimau lives almost exclusively on animal food and fish oil, while the South-sea Islander, who lives most of the time in an atmosphere the temperature of which is higher than the normal temperature of his body, eats chiefly fruits and vegetables. And even in temperate climates, where man lives both on vegetable and animal food, more of the former is consumed during the warm season, while the latter is in preponderance during the cold winter months. The Catholic church has long ago recognized this fact, and has introduced the lenten season, a period of abstinence from animal food, at a time of the year when the seasons change from the cold to the warm, for

if more heat producing food is taken into the system than is required to keep the body at the normal temperature, the digestive system is taxed beyond its capacity, the blood is overcharged with effete material, which is not eliminated quickly enough, and as a result, we feel out of health, which, when it occurs during the first warm days of spring, we call spring fever. The same effect is produced when we change our abode from the North to the South during the winter months, and persist in the same mode of living, and take the same amount of animal food; and if we continue to live this way for a length of time, the result is congestion, and may be abscess of the liver. This is exemplified by the fate of so many Englishmen who go to India, where they eat their roast beef and drink their heavy ales, as they have done in England, but who in a few years have to return with a diseased liver, blaming the climate when they should blame themselves.

In order to oxidize the food, oxygen must be introduced into the system in sufficient quantity, through the lungs, otherwise part of the food only is burnt up and produces heat, while the rest is thrown out again as waste material, and by its presence materially interferes with normal action of the different organs.

Muscular exercise, as is well known, produces heat within the system by a conversion of motion into heat, but this motion depends for its sustenance upon the contractile force of the muscles, which is kept up by part of the food taken into the system. If this contractile force of the muscles is not exercised, it needs not as much nourishment, and the surplus is deposited as fat within and around the different organs. This is exemplified by the fact that in order to fatten an animal, it is kept confined within a narrow space and is overfed.

There can be no doubt that sunlight plays an important part in the oxidation of food within the system, and this is probably one reason why night air is generally supposed to be injurious to delicate constitutions.

This heat, which is generated within the body by the oxidation of food and by muscular movement, would be lost by radiation if the temperature of the atmosphere surrounding the body is far below the normal temperature of the body, and, therefore, this loss must be minimized by interposing between the integuments of the body and the air non-conductors of heat, in the shape of clothing, not to keep the cold out, but to keep the heat in. The face, part of the neck, and the hands are, however, generally exposed, and thereby the epidermis becomes hard and horny, thus becoming a bad conductor of heat, and very little of the systemic warmth is lost by radiation from these parts.

The hydrometric condition of the atmosphere, irrespective of temperature, has a great deal to do with the temperature of the body, at least as far as individual sensation is concerned. We feel more chilly in a cold, damp atmosphere than in a dry one of the same temperature, and we can endure a greater amount of heat when the air is dry than when it is filled with aqueous vapor. As far as I know, this fact has not, as yet, been satisfactorily explained, and I would suggest, as a reason, that the moisture is absorbed by the skin, thus making it a better conductor of heat and facilitating the ingress and egress of heat through it.

We also minimize the expenditure of animal heat by living the greater part of our time (in cities at least) in houses and apartments from which the outer air is excluded as much as possible, and the atmosphere of which, during the cold season, is artificially heated.

The maintenance of the normal temperature of the body, therefore, depends upon the production of heat by oxidation of food within the system, by muscular exercise, and upon the prevention, or at least reduction, of the radiation; and a lowering of this temperature, especially if it be sudden, causes contraction of the capillaries in the outer integuments, a disturbance of the heart's action, and a congestion of some of the internal organs, and particularly of the mucous membrane of the respiratory tract.

Taking it for granted that at a given moment there is a certain quantity of blood in the body which is distributed throughout the vascular system, a greater amount of blood than is normal will accumulate in some portion of the system when a contraction of the capillaries in an area of the surface takes place. Such an accumulation causes an over distention of the capillaries, and consequently a congestion of the part. As examples of this may be cited the facts that deep seated inflammations, or congestions, are relieved by counter irritation of the skin, and it is by no means necessary to apply the counter irritant directly over the organ affected to obtain the desired result; and also, that frequently inflammation and even ulceration of the bowels are a result of extensive burns and scalds of the skin, of the chest, or abdomen. In this latter case the capillaries of the skin are violently contracted and the blood driven to other parts of the body, and especially to the intestines, causing a con-

gestion, followed by inflammation of their mucous membrane.

In connection with, and perhaps caused by, this contraction of the capillaries of the skin by cold there is always an irritation of the distal nerve ends, which, by reflex action, produces a change of the heart's action, which in turn becomes a factor in the production of the congestion in other portions of the body.

The blush of shame is produced by reflex nervous action, the cause of which, however, is central and not peripheral, and not unfrequently is congestion of the lungs produced by violent or long continued emotional disturbances. The reason why the mucous membrane of the respiratory tract is more liable to be the seat of this congestion than any other portion of the body, must be looked for in the fact that it, among civilized nations, is hardly ever free from irritation in one or the o her portion of its extent. We constantly inhale particles of vegetable and mineral substances in the shape of dust, which, by engaging the cilia of the epithelium, act as irritants. This, together with the impure air surcharged with carbonic acid which we breathe in the confined atmosphere of our dwellings and public halls, produce a want of tone in the mucous membrane of the respiratory tract and its capillaries, thus predisposing it to congestion. For as all fluids, so will the blood in the body when pressed upon at any particular point, seek an outlet at the point of least resistance; in this instance the capillaries of the mucous membrane of the nose, pharynx, larynx, trachea and lungs. Catching cold may then be defined as a momentary lowering of the temperature of the body by external influences, which causes both directly and indirectly an uneven distribution of the blood and thereby a congestion or inflammation of internal organs.

Here the question may be raised: Why is it that some persons are more liable to catch cold than others, who, perhaps, are more exposed to cold and the inclemency of the weather?

In order to answer this question I must state that the power of producing heat in the system may be weakened by a number of causes, and that when thus weakened it is not able to produce an extra amount of heat when demand for it is made by exposure to lower temperature. Thus we find that a person who leads a sedentary life and confines himself in an atmosphere artificially heated to from 75° to 80° Fahrenheit, accustoms his system to habitually produce little heat, because little demand is made for it; or one whose digestive apparatus is out of order will not properly digest his food, and can, therefore, not produce sufficient heat by oxidation of the food; or one who is deprived, voluntarily or involuntarily, of the necessary amount of oxygen, be it by being confined in close rooms or on account of disease of the lungs; or finally one who does not take exercise, and so does not produce heat by muscular motion, will easily take cold from the slightest exposure. While on the other hand a person who lives an out of door life, and thus exercises his heat producing faculty, takes cold but rarely, even when much exposed.

To prevent taking cold, therefore, a person should take outdoor exercise at all seasons and in all kinds of weather, should not dress too warmly, should have plenty of fresh air in his house and especially in his bedrooms, and should not heat the air in his rooms above 68–70° F.

There remains much to be said in regard to this interesting subject, but the few hints which I have thrown out have already made a longer paper than I had intended, and I shall therefore close by inviting discussion on it.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

A CLINICAL LECTURE DELIVERED BY WILLIAM GOODELL, M.D.,

Professor of Clinical Gynæcology in the University of Pennsylvania.

REPORTED BY WM. H. MORRISON, M.D.

Subperitoneal Fibroid Tumor of the Uterus.

Gentlemen—Here is a lady with a large tumor. She is thirty eight years old. She says that when this began, three years ago last November, the change of life came. For three years after having her last child the menses were profuse. Now, here is an interesting point to me; here is a solid tumor of the womb, and the menses have ceased. A solid tumor usually causes increased menstruation and delays the menopause.

As far as I can make out, from this external examination, it seems to me to be a fibroid tumor. I can detect no fluid at all. There is no elasticity. It is a dense, hard tumor. It does not cause any pain. She complains only of a distressing feeling across the chest, but I am disposed to attribute that more to some impression on the nerves than to the tumor. When she over-exerts herself, the tumor drops down, the abdominal walls having lost their resiliency, the tumor descends, and then she has trouble with her water.

I do not remember ever having seen a tumor of the womb, as this seems to be, that stopped the menses; the usual course is prolongation of

menstruation. I find that this movable tumor passes down to what I suppose to be the womb, but the sound will be the means of settling that point.

Dr. Leash tells me that a year ago this tumor could not be moved. I asked him if it was lower down then. He says "it was." The reason that it was then immovable, was because it was impacted in the pelvis, but as it grew, it came out of the pelvis and became movable. She then had, I presume, more suffering than at present. She has been brought to me for diagnosis and to see what treatment I think best.

I shall now make a vaginal examination. In the first place, I find that the os is very much larger than it should be. I can pass my finger to the internal os. I cannot, however, get into the cavity. I feel, projecting into the front wall of the vagina, pressing through the bladder, a knob of this tumor. When I move the tumor, it moves the neck of the womb to a certain extent, but only to a certain extent. The attachment of the tumor seems to be pedunculated. I also feel a small polypus in the neck of the womb, a sessile polypus, or perhaps more properly, a little fibroid tumor.

I now pass the sound into the uterus and see if, when I move the tumor, the sound moves. When I move the tumor to that side (the right) there is a very trifling motion imparted to the sound. When I pull it to this side (the left) the sound moves considerably. There is evidently a connection between this tumor and the womb, and the connection is pedunculated, it has length. What inference do I draw from this? It is that this tumor is attached to the right corner of the womb, so that when I pull it toward the left I put the pedicle on the stretch and move the womb, but I have to push it far over toward the right, in order to affect the womb.

I believe this to be a fibroid tumor of the womb, a subperitoneal tumor, originally starting from the surface of the womb and with an attachment o it of some length.

Let us see how far the sound has entered. It measures four inches exactly. I should not be at all surprised to find that in addition to this tumor there were several fibroid tumors in the walls of the uterus.

What is the meaning of this large os? I think that it has nothing to do with the tumor, but is the result of an old laceration.

My diagnosis is, then, a fibroid tumor, subperitoneal in character, with a partly ligamentous attachment to the womb; a possibility, therefore, of its removal.

The next question is, what shall be the treatment? As far as the history goes, this tumor does not appear to be growing. If I should make an abdominal incision and remove that tumor, the woman would run a far greater risk than she would if it was an ovarian tumor. The pedicle of this tumor, although partly ligamentous, is not wholly so, for some uterine tissue passes into the tumor. We shall, therefore, let it be, for the present.

My advice would be to give ergot, in as large doses as she could stand, either the fluid extract by the mouth or Bonjean's extract of ergotine by hypodermic injections, in order to cause condensation of the womb and a diminution of the amount of blood going to the tumor, and so cause it to stop growing or to decrease in size.

If it goes on increasing, there will come the time for the woman to decide as to an operation. We can do nothing now but give ergot, either by the mouth or subcutaneously, and with it I would be disposed to associate muriate of ammonia, giving ten grains three times a day, to see what effect it would have.

I must honestly say, however, that with a pedunculated subperitoneal fibroid tumor, I do not think that treatment by the mouth is going to do much good.

Vesico-vaginal Fistula.

The next case, gentlemen, I got in rather a singular manner. I went to the Pennsylvania Railroad Depot, the other day, to secure a berth in the train, and as I was passing by a colored man, he recognized me, and asked me to go into the ladies' waiting room to see a colored woman who had been there from the previous day, and could not be moved.

I went in, and found her on her knees and suffering great pain. She told me that two or three years ago she had had a severe labor, an instrumental labor; at last, after having been in labor a long time, craniotomy was performed. After her labor she could not hold her water. Her physician could do nothing for her, and she came north to see if anything could be done for her relief.

She had come from the lower part of Virginia, and the hot weather, sitting on the car seats, and the urine trickling over the skin, had so excoriated her person that the skin around the vulva, buttocks, and on the thighs, was raw. This was the cause of her great suffering. I wrote an order and had her brought to the hospital. She was first given a bath, and then I put her on a treatment which I have found very valuable in these cases, that is, injections of a saturated solution of alum into the vagina, and the application to the skin of an ointment of the oxide of zinc, made as thick as possible. Why a thick ointment? Because the thicker it is, the less likely is it to be washed away by the urine. I sometimes use a two and a half per cent. solution of nitrate of silver.

I tried to make an examination, but she made such an outcry that I was not able to obtain any information, except that there was a vesico-vaginal fistula at the neck of the bladder, a very bad place.

She told me that directly after her labor the doctor found a stone in her bladder. If she is correct in this, the stone has been the cause of the fistula, the pressure of the head against the stone has caused the sloughing. I thing that this is a frequent cause of vesico-vaginal fistula. When I say frequent I am using a wrong word, for stone in the bladder is not a frequent disease in women, but I believe that in some cases of vesico-vaginal fistula the fistula is attributable to the fact that there has been a stone in the bladder.

I have not time to go into the history of vesico-vaginal fistula, but it is an opening between the bladder and vagina, allowing the urine to be

constantly dribbling away. It is a great infirmity; the urine causes excoriations, her person is offensive, from the urinous odor, and her clothing is always wet.

What posture shall we put the woman in, for operation? The posture in which the fistula is most easily reached, sometimes directly on the back, sometimes in the knee-breast position; then, again, it is sometimes a good plan to put her on her chest, with the chest resting on a box, as a soap box with a pillow over it, and having her in a kneeling position.

I find that there has been considerable cicatricial contraction here. We have, unfortunately, a very poor light for this purpose, but there you can see the fistula. That little budding you see there, looking like granulations, is the wall of the bladder. Another difficulty we have to contend with is operating in such a small and contracted space.

I shall now begin and denude the surfaces as best I can, and bring them together. This operation will probably not be sufficient to close the opening entirely, so I will, most likely, require another. There are cases that have been operated on as many as thirty times. There is one thing in the way here, that I must be careful not to touch, that is the bladder. I shall take this knife and try to make an incision all the way around, if I can, without hitting the bladder on the opposite side. The bleeding here so interferes with the operation that I shall try the scissors. If this operation was performed on the surface of the body, it would be exceedingly simple, but being here, in a confined place, it is exceedingly difficult. This is an operation which I very much dislike to perform before you, for two reasons. One is that you can see very little, the other is that I have to take time and do this slowly, and knowing that you are weary of it, the tendency is to hurry too much; but still, it is necessary for you to see the operation, its mode of performance, the position of the woman, and then you may learn something as we go along.

Now, gentlemen, while a sponge is being held firmly over this, to stop the hemorrhage, let me talk a little on the subject of vesico-vaginal fistula. It is produced by delay on the part of the physician; that is, in nine cases out of ten the fistula is caused by the physician not applying the forceps, or not performing craniotomy soon enough. I wish you to bear that in mind. It is delay in the second stage of labor, for no matter how contracted the pelvis, if the bag of waters is unruptured there is no danger of sloughing. By the by, this accident does not usually occur in women with very small pelves, but where the pelvis is under-sized, for it is necessary that the head should get into the pelvis in order to produce a fistula.

The question arises, How long must you wait before interfering? That is a very difficult question to answer. If there is any progress of the head, then by all means wait or put the forceps on. As I say, it is usually caused by not putting the forceps on soon enough; either because the physician is afraid or the family object to it. Under circumstances of that kind, I advise you to send for another physician. While rupture of the perineum is frequently due, as I have told you before, to the use of the forceps, vesico-vaginal fistula is due to the non-use of the forceps.

The bleeding here is quite profuse, and we rely upon our stitches to stop it, but sometimes we cannot stop it in that way, and then the operation fails. We cannot apply a ligature to these little arteries, for if we did there would be a failure of union.

The light is so poor here that I shall finish this operation before a window in the next room. I have got this tolerably well denuded, but I am going to go over it again, carefully. It will probably take another hour before it is finished.

There is another thing about these operations: they are exceedingly unremunerative. I have performed this operation a great number of times, but all the money I ever received was $40, for two operations on the same woman. Dr. Emmet, of New York, told me, I am not quite certain about the figures, but I think it was that his first one hundred and fifty operations paid him only $300, an average of two dollars for each operation.

What does this mean? I think that it reflects a little on our profession. It means that these fistulæ occur in poor women. A physician is called to a poor woman; the head does not descend; he has a number of patients and he leaves her for awhile and goes to see them. If that were a rich patient, he could not do so. He comes back again in a couple of hours, but still there is no progress, and he goes out again; so in this way there is a certain amount of neglect. The question may arise in his mind, "shall I send for Dr. Smith?" Perhaps Dr. Smith lives five or six miles away, or he thinks that Smith will make fun of him, and so he does not send. If that was a rich patient and the head was delayed, the family would insist upon him sending for another physician, and he would be willing to do so, for there would be a responsibility in this case much different from that in the poor woman's. Occasionally fistulæ occur in women of position, but this is the exception.

Now, when you get into a scrape of this kind, and the head will not descend, your best plan is to send for some one else to share the responsibility with you. I have been in positions where I would have given all my old boots and shoes, and something over, to have had a friend with me, to share the responsibility. In other cases, I have been ashamed to send for a friend, fearing that he would make fun of me.

I shall now simply tell you what I shall do, and finish the operation in the other room. After I have denuded the surface carefully, I shall pass the needles, taking care not to put them through the whole thickness of the mucous membrane, but simply from one edge to the other. I do this for two reasons: first, the needle might cause troublesome hemorrhage from the mucous membrane, which is very vascular, as you have seen. Secondly, each one of the punctures might possibly produce a little fistula if I passed the needle through the entire thickness of the wall of the bladder. I shall have a large number of stitches, probably, thirteen or fourteen. I shall shot each one and leave them in a week. I shall put a catheter into the bladder, to allow the urine to escape as fast as it is secreted.

Medical Societies.

AMERICAN MEDICAL ASSOCIATION—32d ANNUAL MEETING.

Proceedings of Sections—Second Day.

In continuation of last week we give the Proceedings of the various Sections, condensing them as much as practicable, owing to the pressure upon our columns from other material. Some of the papers read will be referred to in more extended abstracts in future numbers of the journal.

On State Medicine.—A paper on the National Board of Health and the International Sanitary Conference of 1881, was read by Dr. J. L. Cabell, which gave a résumé of the work of the National organization and explained the reasons for calling the Sanitary Conference.

Dr. C. F. Folsom read an able and interesting paper on the Relation of the State to the Insane, which advocated the establishment of State boards of lunacy, composed of experts in insanity and its treatment.

These papers were discussed freely and referred to the Publication Committee.

Surgery and Anatomy.—Dr. C. F. Stillman, of New Jersey, presented his Sector Splint, adapted to different parts of the body.

Dr. Alfred C. Post, of New York, reported two cases of "Plastic Operation on the Face," and described the method of operating.

Dr. D. H. Goodwillie, of New York, read a paper on Treatment of Anchylosis of the Temporo-maxillary Articulation, which elicited considerable discussion, in which removal of a wedge-shaped piece of the ascending ramus was advocated by Prof. Gross and Hunter McGuire.

Dr. L. A. Sayre applied a plaster jacket to a case of lateral curvature, to demonstrate his method of treating spinal disease.

The Chair appointed as members of the Prize Award Committee from this Section, Drs. Kinloch, South Carolina; Pratt, St. Louis; and Burgett, New York.

Diseases of Children.—The discussion of treatment of "Eczema of Infants" was continued by Dr. Jacobi, of New York.

A paper on the "Treatment of Diphtheria" by Dr. Nunn, of Savannah, was read by the Chairman, in which insufflation was strongly recommended. A powder used is as follows:—

℞.	Sulphur sub.,	gr. xlviij	
	Acid tannic,	gr. xij	
	Acid salicylic,	gr. j	
	Pulv. potass. chlor.,	gr. xij.	M.

Precaution must be used in compounding this prescription. A little of this powder is put on the back of the tongue every hour or two, and a small piece of ice given afterwards. It will be seen that this prescription is a combination of antiseptics principally.

In another case treated by Dr. Nunn, the following formula was used with good effect:—

℞.	Sulphur,	gr. vij
	Acid boric.,	gr. iv
	Acid tannic,	gr. j
	Acid salicylic,	gr. j
	Resorcin,	gr. j.

Another formula is:—

℞.	Sulphur sub.,	gr. viij	
	Acid boric,	gr. iv	
	Acid benzoic,	gr. j	
	Acid salicylic,	gr. j	
	Acid tannic,	gr. j	
	Acid tartaric,	gr. iv	
	Sodii chlorid.,	gr. iv	
	Resorcin,	gr. j.	M.

The subject led to a general discussion, during which the chairman expressed an opinion unfavorable to the use of pilocarpia, and also said that he did not have as much confidence in lime water as some appear to have.

Dr. E. H. Bradford, of ——, presented a clinical report of two cases (aged eleven and thirteen years respectively) of "Resection of the Tarsus in Severe Club Foot," with excellent results in each instance. The operation was resorted to after tenotomy and all ordinary treatment had failed to relieve the deformity.

Practice of Medicine.—The afternoon was devoted to the discussion of the etiology and treatment of pneumonia, after the reading of a paper on this subject, by Dr. Wm. C. Dabney. Diverse opinions were expressed, and no agreement was had upon the causes, nature, or magistral treatment of the disease.

A paper on the Nature and Treatment of Pulmonary Phthisis, by Dr. B. Robinson, of New York, was read by title.

Ophthalmology, Otology and Laryngology.—Dr. Carl Seiler read a clinical paper on Syphilitic Laryngitis, in which he pointed out the diagnostic points afforded by the red areola of the mucous membrane, and the symmetrical disposition of the ulcers. He recommended general and local treatment.

Dr. Chisholm read a paper describing a peculiar form of Tinnitus Aurium caused by rhythmical contraction of the tensor tympani muscle, caused by stimulants, reflex irritation, etc.

Dr. Eugene Smith, of Detroit, reported a plastic operation for the relief of ectropium, when the piece of cutis vera was transplanted from the arm of the patient, with success.

Dr. H. Augustus Wilson, of Philadelphia, exhibited some pellets of atropia (gr. 1–100), which were adapted to ophthalmic use, for relaxing the accommodation. A number of different varieties of these pellets are made for hypodermic use.

A paper from Dr. Laurence Turnbull, of Philadelphia, was read by title. Otitis Intermittens, with Observations upon the use of Quinine in Diseases of the Ear; On the importance of Ear Examinations in Effecting Life Insurance.

Obstetrics and Diseases of Women.—A question to the chairman led to an interesting discussion on the question of the investing capsule of uterine fibroids.

Dr. H. P. C. Wilson exhibited some gynæcological instruments to the Section, and Dr. H. O. Marcy, of Mass., exhibited a double drainage tube for continuous irrigation.

Third Day.

Surgery.—Dr. B. A. Watson, of Jersey City, read an elaborate paper on Traumatic Fever, in

which he detailed a number of experiments. He concluded that there was a septic and a non-septic form, each of which required appropriate treatment.

Labial Carbuncle. was the title of a paper by Chas. A. Leale, of New York, in which free incisions and nitric acid applications were highly recommended.

Ophthalmology, Otology and Laryngology.—The chairman made some remarks upon Astigmatism, which led to a general expression of opinion.

A paper on the Treatment of Nasal Polypi, by D. S. Reynolds, was read by title and referred.

Obstetrics.—Can we make a positive diagnosis of pregnancy prior to the audible sounds of the fœtal heart, and the detection of fœtal movements? was discussed by Dr. Jas. Tabor Johnson, of Washington, who, after enumerating the ordinary symptoms, concluded that the increase in the temperature of the vagina offered the most certain indication.

A number of instruments of original devices were shown by Paul F. Mundé, of New York, which were discussed up to the time of adjournment.

Practice of Medicine.—Dr. L. D. Bulkeley read a paper on Diet and Hygiene of Eczema, which admirably supplemented the paper of Dr. White, read before another Section.

The treatment of Diphtheria was discussed by Dr. Whittaker, in a paper recommending quinine, salicylic acid, or the benzoates, internally, and the local application of Monsel's solution.

Dr. J. A. Octerlony read a paper on the Treatment of Dysentery.

Dr. S. E. Atkinson read a communication on the Production of Albuminuria by large doses of Iodide of Potassium. These papers led to considerable discussion of great interest.

Dr. Henry A. Martin described a case of true variola equinæ, and read a paper on Variola Vaccinæ and Variola Equinæ in Massachusetts. He also read an extract from the *College and Clinical Record*, on Pseudo-vaccination, and after discussion moved that a committee be appointed by the Association to visit these various farms and investigate the whole subject of the supply of bovine virus," which was adopted.

Dr. F. E. Stewart read a paper on the Materia Medica of the Future.

On motion of Dr. Dunster, of Ann Arbor, it was

"*Resolved*, That the spirit of the code of ethics forbids a physician from prescribing a remedy controlled by a patent, copyright, or trademark. This, however, shall except a patent upon a process of manufacture, or machinery, provided patent be not used to prevent legitimate competition; and shall also except use of a trademark used to designate a brand of manufacture: Provided, that the article so marked be accompanied by working formulæ, duly sworn to, and also, by a technical, scientific name, under which any one can compete in manufacture of same."

Dr. Upshur, of Richmond, Va., read the report of a case of paralysis of motion of both upper extremities, in which the prominent symptoms were complete paralysis of motion of both upper extremities, *except in the hands*, intense pain in the shoulders on any attempt to lie down, and inability to sleep. The attack was ushered in by convulsions, epileptic in character.

Dr. H. Augustus Wilson, of Philadelphia, presented his Soluble Compound Pellets for Hypodermic Use and General Medication.

State Medicine.—Papers on "Cellars," by A. N. Bell, and on the Necessity and Means of Removing Putrescible Matter from Inhabited Places, by Dr. Wright, of Milwaukee, were read by title.

Diseases of Children.—Dr. Blake, of Massachusetts. read an interesting communication on Middle Ear Disease in Children in the course of the Acute Exanthemata.

Dr. Jacobi read his address on Children's Diseases, which referred particularly to the eruptive disorders, and claims for rubeola (German Measles) a distinct place among them. He also condemned the free use of chlorate of potassium, and mentioned the fact that several deaths have been caused by its employment.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Stated meeting, held at the house of Dr. J. Solis Cohen, on Friday, April 22d, 1881.

Before the meeting was opened, Dr. Cohen stated that the case exhibited at the last meeting, by himself, had proved to be one of tuberculosis and not of syphilis.

Dr. Chas. Turnbull then exhibited a case in which basilar fracture of the skull is suspected, produced by a crushing force applied to the neck, which shows peculiar, ocular, auditory and laryngeal symptoms. The Dr. stated that he would furnish a detailed account of the case at the next meeting of the Society.

The President, Dr. Cohen, then called the meeting to order, and after the minutes of the previous meeting had been read and approved, Dr. Carl Seiler read a paper on "Catching Cold," which was discussed by most of the members present.

Dr. Turnbull then exhibited a new form of ear trumpet and audiphone combined, which was the mouth piece of a Waat's telephone. The Dr. suggested the name of "Tympanphone" for the new instrument. He then reported a remarkable cure of specific ozæna by smoke from a wood fire.

Dr. Seiler next exhibited a new galvano cautery knife, which was insulated with vulcanized fibre, a substance which is not affected by heat and which is a non-conductor of electricity. Dr. Cohen, in the discussion which followed, said that he was glad that Dr. Seiler had used such a substance, for he had found that the silk generally used to insulate the two conducting wires did not afford sufficient protection to the parts not to be cauterized, and was, besides, easily burned off.

Dr. Bean then, by permission, exhibited a specimen of a larynx from a patient who had died of phthisis, and who had coughed up two pieces of bone, which, after having been examined by the members, and it having been found that in the specimen the cricoid cartilage was denuded of mucous membrane and the arytenoid carti-

lages were missing, were pronounced to be the ossified arytenoid cartilages.

The Society then went into private session.

CARL SEILER, *Secretary.*

EDITORIAL DEPARTMENT.

PERISCOPE.

On Shock.

In M. Furneaux Jordan's recent work, entitled "Surgical Inquiries," Shock is defined as a peculiar condition of the animal system, characterized by depression of all its functions, the result of a powerful impression applied to the nervous centres, or to a portion, more or less considerable, of the peripheral nervous expansion. The author's view is, accepting the correlation of forces, physical and vital, that as the result of this impression there is a conversion of nerve force into some other force, and in this way the functions of the body become depressed, from want of nerve force. This is no doubt a very plausible view, but it hardly seems the most probable. Granting that shock is caused by, or is intimately related with, a deficiency of nerve-force, is it not more probable that this force is not manufactured—*i.e.*, that the physical or other vital forces are not changed into nerve force—while the patient is suffering from shock, rather than that nerve force is manufactured and then rapidly changed into some other force? Such a view would surely agree better with the great depression or abolition of function throughout the body which is so characteristic of shock.

The author thinks that shock arises from impressions produced on the cerebro spinal system rather than on the sympathetic system, and he looks on the "*Klop-versuch*" of Goltz as indicating the effects of impressions on the pneumogastric nerve rather than on the sympathetic ganglia. At the same time he admits that a powerful impression on the sympathetic nerves may give rise to shock. How far this view is justified is doubtful, and we can hardly admit that in Goltz's experiment the effect was due to the injury done to the pneumogastric rather than to the sympathetic. And the author demonstrates that in amputation the shock occurs, or is greatest, when the bone is divided. Here it is surely sympathetic rather than cerebro-spinal fibres which are affected.

The effects of mental shock, more especially when combined with bodily injury and shock, are well brought out by the author. This is seen in injuries to healthy persons, where the patient has time to realize the approaching danger, or afterwards to picture to himself the future results of the mutilation.

Some very interesting thermometric and sphygmographic observations made on patients suffering from shock are given; and the ulterior effects of shock and the condition of chronic shock are carefully described. The physiological and pathological phenomena of shock are discussed at length.

In the treatment of shock the author chiefly advocates heat, in the form of hot-water bottles, applied, not to the feet only, but to many parts of the body. Stimulants are also recommended, and the combination of opium with them is also advised. When the heart has ceased to beat, he believes, from experiments on animals, that it might be possible to restore its action by means of a rapid puncture with a long, sharp needle.

A Case Illustrating "Missed Labor."

At a recent meeting of the Obstetrical Society of London, Dr. Barnes stated that the term, "missed labor," proposed by Oldham, was not justified by the facts of Oldham's case, which proved on autopsy to have been one of extra-uterine gestation. Discussing other cases of presumed missed labor, accepting the arguments of Stoltz and Muller, the author affirmed that no authentic example of missed labor—this term being taken to mean the prolonged retention in utero of a fœtus, living, at term—is yet known. He cited examples of the retention of the ovum, which had perished in utero at a pre-viable age, for some time, and notably until the arrival of the natural term of gestation. He related a case which came under his own care:—

A lady, aged thirty-nine, had borne three still-born children, the last of them five years ago, before consulting Dr. Veitch, at Penang, in December, 1872. Pregnancy dated from early in November preceding. The usual signs of pregnancy were manifest; she verified quickening; and up to the seventh month she felt movements of the child. About the eighth month, after a slight accident, a flow of blood came. Three weeks later another bleeding occurred, but no labor pains. Eleven months after the presumed date of conception she came to England. There was an impression that she might be suffering from fibroid of the uterus. She came under the author's care in December, 1873. Under chloroform, the cervix uteri having been dilated by laminaria tents, he felt what he took to be the interior surface of the uterus; the sound passed six inches. In January, 1874, some colored discharges went on. Pieces of bone, which turned out to be bits of the spinal column, passed by vagina. After dilatation by tents, more bones were removed by fingers and forceps. In February this manœuvre was repeated, and by craniotomy-forceps the remaining parts of a fœtus, which appeared to have reached the eighth or ninth month of gestation, were extracted. Her health then improved, the discharges became less offensive, and the uterus gradually shrank, as in ordinary involution, but more slowly, until it reached the common conditions of the non-pregnant state, and the pa-

tient perfectly recovered. The author submitted that this was a clear instance of the retention of a fœtus dying in utero at a viable stage, for some months after the normal term of gestation had been reached; and that in this sense the term "missed labor" might apply.

Excessive Eating as a Cause of Disease.

Some just remarks on this point are made by Dr. Liveing, the well known dermatologist, in the *Lancet*. He observes:—

I frequently meet with cases of intractable eczema pudendi in women past middle life, of sedentary habits, and eating three large meat meals a day, and trying by all means in their power to stimulate their appetite, under the erroneous impression that they are "keeping up their strength." Now, in these and similar cases, medicine and local treatment are almost equally useless, unless there is, at the same time, a thorough reform in the diet. The first point is to deprive the patients of sugar as an article of food, except just enough to make light puddings palatable. The reason for this is that much of the sugar passes the liver unchanged, and is therefore worse than useless as a food. The next point is greatly to reduce the animal food, especially mutton and beef, and to substitute for it simple clear soup, and poultry or fish in moderate quantity once a day. Lastly, the chief part of the daily diet should be made up of light farinaceous and milk food, such as bread, rice, and macaroni. This is, I know, contrary to the view often entertained, that saccharine urine should be treated by an animal diet, and that starch should be as much as possible excluded. Now, whatever good may result from such a diet in some cases, I am quite sure that it does not answer in those to which I refer; on the contrary, exactly the reverse holds, and the old routine practice, except so far as sugar is excluded, is quite wrong. I have seen the sugar disappear from the urine and the eczema depart under a change of diet such as I have above recommended. The truth is that many people at sixty, when the tissue changes are slow, eat as much, or more than they did at twenty, when all the process of change are at the height of their activity; what wonder, then, that unnatural work is thrown upon the skin, kidneys, and other excreting organs of the body. There is some substantial truth in the saying that small eaters live the longest.

Types of Imbecility.

In February last, at a meeting of the Harveian Society of London, Dr. Fletcher Beach read a paper "On Types of Imbecility." The author commenced by referring to the different systems of classification of cases of imbecility which have been adopted and brought forward, one of which, by experience, he had found useful in describing the disease. Cases under this system are classified under the headings of congenital and acquired imbecility, including under the former those occurring at the time, under the latter those supervening after birth. The following classification was the one suggested by the author: *Congenital Imbecility.*—1, Simple congenital; 2 Microcephalic; 3, Hydrocephalic; 4, Scalphocephalic; 5, Pearly tic; 6, Cretinism (sporadic, endemic). *Acquired Imbecility.*—1, Eclampsic; 2, Epileptic; 3, Hydrocephalic; 4, Paralytic; 5, Inflammatory (*a.* Hypertrophic); 6, Traumatic; 7, Cretinism (endemic). It was shown that under the heading "Simple Congenital Imbecility" are included cases of a very low, and others of a fairly high type. The cause of microcephalic imbecility was discussed, and the difference between the hydrocephalic and rickety head was pointed out. The cause of scaphocephalic imbecility was said to be obscure. Pearly tic imbeciles were shown to make good progress mentally, but little physically. The characteristics of sporadic and endemic cretinism were usually the absence of a thyroid gland, and generally the presence of fatty tumors in the posterior triangles of the neck. More improvement was stated to take place in cases of acquired than in congenital imbecility, and the reason for this was explained. Eclampsic imbecility was shown to be due to convulsions coming on soon after birth, continuing some years and then ceasing, but so injuring the structure of the brain during their continuance that the patient becomes imbecile. Under the heading "Epileptic Imbecility" are included some cases where, with cessation of fits, the greatest improvement takes place, and others who go on from bad to worse and finally end in utter dementia. Inflammatory imbecility was said to be due to measles, typhoid fever, and other acute diseases, as a result or complication of which inflammation of the brain and membranes was produced, not sufficiently grave to be fatal, but serious enough to cause mental impairment. The reason for placing hypertrophic imbecility in this class was explained, and the difference between hypertrophy of the brain and chronic hydrocephalus was pointed out. Traumatic imbecility was stated to be due to some injury of the brain, hereditary predisposition acting as a predisposing cause in these as in other cases where a slight exciting cause seemed scarcely sufficient to produce so grave a result.

The Treatment of Gout.

Mr. A. Meldon, M.R.C.S., writes to the *British Medical Journal*, March 26th, 1881:—

Looking on gout as having a predisposing and exciting cause, it naturally follows that we may cure the affection by either of two plans, as directed against one or other cause. I invariably commence my treatment, when my patients are strong, by taking from four to eight ounces of blood from the arm; and repeatedly I have found the pain subside while the blood was flowing, and not again return. A purge then follows, with colchicum: and then I resort to more tonics. Phosphate of quinine is my favorite; but sulphate of nickel, phosphorus, strychnia, or copper, may be used in cases where quinine will not agree. I always order occasional doses of quinine as a preventive. I have found a ten-grain dose of sulphate of quinine cut short an attack.

In one case which fell under my notice, the patient stated that an electric shock had com

pletely relieved him of pain; and in another case the patient was in the habit of inhaling oxygen, and stated to me that it always shortened the attack.

There is one more point on which I wish to touch; that is, the power of the skin to eliminate uric acid. If a considerable quantity of the cutaneous secretion be obtained and evaporated, abundance of crystals of urate of soda will be obtained. In a Turkish bath, with the aid of a watch-glass, this can readily be obtained.

The conclusions which I would draw from this paper are as follows:—

1. The presence of uric acid and soda in the blood is not the sole cause of gout.
2. Want of exercise and animal diet will produce an accumulation of uric acid in the blood.
3. Uric acid and soda must exist in the blood before the disease can be produced.
4. There must be depression of the nervous system to cause an attack of gout.
5. Depression of the nervous system causes union between uric acid and soda, forming urate of soda.
6. When an attack of gout has passed away, it does not necessarily follow that the uric acid has disappeared from the blood.
7. Uric acid may exist in the blood in considerable quantities, and for any length of time, without causing gout.
8. The use of nerve tonics, as quinine, strychnia, and caffeine, and such like, as well as the inhaling of oxygen and the use of electricity, are of much service in the treatment of the disease.

Symptoms of Cantharides Poisoning During its Internal Administration.

Mr. T. F. Clarke, M.R.C.S., England, writes to the *Lancet*, March 26th:—

The two following cases, exhibiting symptoms of poisoning by cantharides during the later treatment of gonorrhœa, may be of interest, on account of the favorable result in each case.

I may preface my remarks by stating that in nearly every case of gonorrhœa, for the primary symptoms, *e. g.*, scalding, chordee, etc., with thick discharge, I prescribe saline medicines and tepid-water injections. When the discharge becomes thinner, and all active inflammation has abated, I prescribe iron and cantharides internally (tincture of the perchloride of iron and tincture of cantharides, of each five minims, three times a day), and an injection of sulphate of zinc (two grains to the ounce). Such was the course followed in the present instances.

In the first case my patient had been taking the cantharides mixture for five days, at the end of which time he was virtually cured. A week after the discontinuance of the medicine I was summoned to him for violent pain over the bladder, and this was accompanied, on the following day, with strangury. These symptoms, at first very severe, passed off at the end of about four days, during which time I gave him nitric ether and hyoscyamus, internally, and ordered hot baths whenever the strangury came on.

In the second case the patient, after taking two doses only of the cantharides mixture, had some of the symptoms of poisoning, viz., frequent desire to pass urine, burning pain during micturition, which was very difficult, and always accompanied towards the end of the process by a few drops of blood. I ordered him to take only half the dose, but these directions were not followed, and he continued with the full dose, the symptoms, nevertheless, rapidly abating.

In each case every trace of the gonorrhœa was removed, and as soon as the active symptoms produced by the cantharides passed off, the patient felt as well as ever, and had not the slightest discomfort in the urinary organs. Why these symptoms of cantharides poisoning should have presented themselves—for I frequently administer the drug in much larger doses, and without any untoward symptom—I am at a loss to understand. The delay of the symptoms in the second case may, I think, be explained by the supposition that the drug became stored up in the kidneys, and that after a short time its cumulative action gave rise to the poisoning symptoms.

Iodoform in Nasal Catarrh.

Dr. B. T. Mouser, of San Francisco, gives this case in the *Western Lancet*:—

H. B., aged 14; exposed in occupation to constant inhalation of fine emery. Patient called on me in April, complaining of offensive breath, occasional headaches and epistaxis. The fossæ dry and lack of secretion, epiphora caused by closure of the punctæ lachrymalis. On examination anteriorly with nasal speculum and posteriorly with small mirror, much after the style commonly used in laryngeal examinations, the fossæ are found to be roomy, pituitary membrane dry, and lacking that glistening appearance seen when there is sufficient mucus. On the posterior aspect of the septum and margin of the turbinated bones a varying amount of thin, white crusts are seen, which it is impossible for patient to free himself of by hawking down the throat or blowing the nose. Expired air is very offensive, so much so that the disagreeable odor is noticed immediately on patient's entering the room. Sense of olfaction so thoroughly blunted that this most obnoxious symptom of the disease is not apparent to himself, but is often mentioned by his friends and relatives. The punctæ lachrymalis being opened, after the lapse of three or four days all indications of epiphora disappeared; it not being necessary to dilate the canalicula or sacs. Nasal douche was used for many months, and applications of the numerous disinfectants made—carbolic acid and glycerine, permanganate of potash, salicylic acid—all proving of no avail. Pellets of cotton-wool, saturated with iodoform, carbolic acid and vaseline were placed in the superior meatus from behind and removed every second day. Iodoform acts on the pituitary membrane as a tonic and stimulant, and while it is a disinfectant, its own not pleasant odor is disguised by the remaining two ingredients. After the removal of each pellet the full expanse of pituitary membrane was thoroughly washed with a spray of the ten per cent. boracic acid solution. During the first month of treatment it was frequently found necessary to remove some deposits of incrustation on the turbinated bones

by means of brush introduced into the posterior nares.

For some time the patient has been free from headaches and epistaxis, the offensiveness of expired air is not apparent to members of his family; and during the last two months the most thorough examinations have not revealed any fetid and tenacious crusts.

On Sudden Death in Cases of Hysteria.

At a meeting of the Medical Society of Paris, M. Raynaud reported (*Revue Méd.*, quoted in the London *Medical Record*, March 15th), a case of sudden death, which had occurred, as he stated, in the midst of a hysterical attack. The woman was thirty-seven years old, unmarried, and had long suffered from very singular attacks of vapors, and, from time to time, formidable attacks of hysteria. She had eczema of the foot and hand, which seemed to excite attacks. On each occasion she was seized with laryngeal spasm, like that of hydrophobia, and plunged her nails into the flesh of her hands. Fragments of nails had frequently to be extracted from the flesh; but, on the last occasion on which this was done, she complained, on the following day, of severe pain in the back, like the true 'hysteric clavus.' She was feverish; temperature above the normal; pulse frequent. A blister was applied, and dressed with morphia. The next day the pain had changed its place; it was in the neck, and excited trismus and howling exclamations. The patient preferred the sitting position, and suffered extremely when the head was moved. She took from five to six centigrams of morphia a day, by hypodermic injection. Two days passed; the symptoms increased in extent; pharyngeal spasm followed, with frequent expectoration or trismus, and dyspnœa set in. The slightest touch excited her to fury. Her character changed; she became insolent and abusive. She presented an absolute picture of hydrophobia. Careful inquiry showed that she had not been bitten, and that no dog had been in the house. Two days afterwards the pain changed to her abdomen, and remained there for three or four days, accompanied by contraction of the diaphragm and arrest of breathing without thoracic expansion. Finally, on the following day, the patient was livid, cyanosed; her pulse was imperceptible; she was groaning, and her agony extreme. The next morning she was a little calmer. Towards the middle of the day a fresh spasmodic attack occurred, to relieve which artificial respiration was vainly employed. The patient succumbed, in spite of all that could be done.

On Catarrhal Diphtheria.

The observations of Dr. Marx on this form of disease are given in the London *Medical Record*, March 15th.

He defines it as that form in which there is only superficial and unlimited diphtheritic membrane combined with simple catarrh of the mucous membrane, slight constitutional symptoms, inconsiderable glandular swelling and limitation of the disease to the throat. That it is a true diphtheria, he considers, is shown, (1) by its clinical character; (2) by its not unfrequently passing into the severer forms; (3) by its infective power; and, lastly, (4) by its microscopic pathology. The disease begins with slight fever, malaise and pain in swallowing. The mucous membrane of the throat at some part, generally the tonsil, is swollen, red, and has on it one or more grayish spots like hoar-frost. These spots are superficial, limited, and disappear in two to three days, rarely lasting six days; unless, as sometimes occurs, the disease passes into the severe form with thick and spreading membrane. Microscopically these spots are found to consist of colonies of micrococci, which pass through the comparatively unaltered superficial epithelial layers into the deeper layers where the cells are swollen up and contain large nuclei. After twenty-four hours, pus forms in the deeper layers, and the superficial layers are thrown off. Catarrhal diphtheria differs from the severe form in the absence of a fibrinous exudation between the epithelium, and from simple catarrh of the mucous membrane by the presence of micrococci in place of the numerous organisms in catarrhal muco-purulent secretion, such as leptothrix buccalis, oidium albicans, etc. In the treatment of this affection, the author recommends (1) immediate isolation of the case, notwithstanding apparent mildness; (2) frequent inhalations of steam; and, (3) disinfection of the mouth with gargles, etc. Astringents ought to be avoided, as checking the separation of the membrane, which is furthered by a rapid formation of pus under the influence of warm inhalations.

Treatment of Lupus and Rodent Ulcer.

Dr. J. Ferguson writes, in the *Canada Journal Medical Science*, March:—

Lupus may sometimes be due to a syphilitic taint; but it is very doubtful if rodent ulcer can ever be traced to such a cause, and the few cases occurring in a syphilized constitution may be mere coincidences. In such cases, it is clear, "specifics" will avail very little. The proper use of caustics is also beneficial; yet they should seldom or never be alone trusted to, as local means of radical cure. I purpose briefly to give the results of observations on the operations of others, and my own experience in two cases of lupus and one of rodent ulcer.

The operative treatment is very simple, and is as follows: After the patient is anæsthetized, the whole of the diseased tissues are freely and thoroughly removed with a Squire's scarificator, or a Volkmann's spoon, and the fresh surface well touched with a solution of chloride of zinc, of the strength of 40 grains to the ounce, or nitric acid may be used in its stead. If the operation be near the mouth or nose, the patient ought to be allowed to recover pretty fully from the anæsthetic before the application of the caustic, lest any of it should be swallowed. A light water dressing is then used, and a healthy granulating surface springs up in a few days, on which any of the ordinary plastic operations can be performed.

I have seen the above operation about two dozen times; and, so far as I have been able to ascertain, with universal success. It has been

done by myself on a case of lupus non-exedens, one of lupus exedens and one of rodent ulcer. The two former are completely cicatrized, while the latter exhibits a healthy healing surface. These affections being purely local, their removal can be made complete and the cure thorough.

An excellent after dressing may be made by soaking thick, soft lint in a saturated solution of boracic acid, and applying it to the wound. This dressing is a clean, non-irritating, and, at the same time, antiseptic one.

Hemorrhage from the Rectum Treated by Pyrogallic Acid.

In the following case, says Dr. Wallace, in the Glasgow *Medical Journal*, I tried the remedy as recommended in the above "Item," with the best results:—

A young lady had, for four or five years, suffered from an almost daily, though, as a rule, slight discharge of blood from the rectum. A doctor was consulted, and the question of piles was raised, but she would not permit an examination to be made. Her health, naturally good, began very gradually to be affected, but as the hemorrhage was at no particular time excessive, she still delayed treatment. It having, however, increased of late, she consulted me, and I ascertained the following facts: 1. The discharge presented all the characters of fresh blood, and came away equally freely and without warning, whether the patient was lying, sitting, or taking active exercise. 2. There was not, and there never had been, the slightest pain in the bowel on defecation, nor did the bleeding occur specially at that time. 3. Though, as a rule, of almost daily occurrence, the hemorrhage sometimes ceased for three or four weeks. 4. The catamenia were quite regular. On general grounds, I was certain of the accuracy of her statements. (These conditions seem to point to some lesion of the rectum, or at least the lower bowel, and yet preclude the idea of piles, fistula, or even of polypus.) Before insisting on an examination, I tried the ordinary astringents and hæmostatics, including ergot, but without any result except causing nausea. I then gave pyrogallic acid in one grain doses three times a day. This was readily taken in water, without causing the slightest derangement of the stomach, and in one week bleeding had completely ceased. For a few days after its cessation she had a feeling of uneasiness in the loins, but this soon went away. It is two months since then, and she continues perfectly well.

Salicine in Acute Rheumatism.

Dr. Chas. Jas. Fox, of Willimantic, Conn., writes to the *Indiana Medical Reporter*:—

Inasmuch as the treatment of the above affection is so unsatisfactory, any therapeutic agent which is successful in arresting the course or diminishing the complications of so common an affection cannot be too much valued, or too well appreciated. During the past four years I have had wonderful success by the use of the salicine n these affections. From a review of some seventeen cases allow me to show the results I obtained by a history of the following case:—

Mrs. A., aged 32; June 8th, was taken with all the marked symptoms of rheumatic fever; extensive effusion was found in both joints, with œdema of the ankles, wrists, metacarpal and phalangeal joints; she complained of great pain; at my first visit the temperature was 102°, pulse 110 and respiration 33; at 9 P.M. the same day her temperature was 103°; I had her placed on salicine, grs. x, every two hours. June 10th the temperature had fallen to 100.5°. I increased the salicine to 15 grs. every two hours. June 11th, physical examination showed a displacement of the apex of the heart downward and upward, with a systolic bruit over it. June 12th, temperature ranges from 102 to 103°, pulse 120, respiration 40; I increased the salicine to grs. xx every two hours. June 13th, temperature had fallen to 100.5°. June 15th, pulse, temperature and rest quite normal. This was her second attack; the first attack lasted six weeks. As far as my experience goes the salicine treatment seems to me to be the true desideratum in these affections, and, if given early, prevents all cardiac complications, and that its free administration is the best means of staying the progress of these complications should they occur.

Moreover, the value of the salicine plan of treatment should be determined not by the results obtained in a certain number of cases, but by the general verdict of the profession.

How to Vaccinate.

Dr. B. Dozier describes the details of this little operation as he performs it (*Independent Practitioner*, March, 1881):—

My percentage of successful vaccinations so far surpassed my expectations and also that of my colleagues, who used the same virus as myself, but a different mode of scarifying the surface, that I have concluded failures in vaccination should be more frequently attributed to an improper mode of scarification than to poor or ineffective virus, or a "peculiar condition of the system."

I use *only fresh bovine virus*, and prefer the ivory points to any other. I dip the point to be used in *cold water*, then lay it aside, in order that the virus coating may become well dissolved or softened. In the interim I scarify with a dry ivory point, stroking very lightly, scraping off as completely as possible, *without bringing blood*, the cuticle or scarf skin, for a space of about a quarter of an inch square. I then rub over the abrasion the previously prepared point, until the virus is all off, and insist on the sleeve being kept up for at least five minutes after the operation. I then place over the part a piece of adhesive plaster of sufficient size to cover well the scarification. Out of two hundred and twenty-five vaccinated adults and children, and many of the former having been successfully vaccinated before, I got a result of *ninety-seven* per cent. of successful vaccinations! While my colleagues, who used lancets, principally, with which to scarify and *cut*, rather than *scrape* through the outer skin, consequently causing more or less bleeding, were successful in not more than fifty per cent. of their cases.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE THEORY OF MATERNAL IMPRESSIONS.

The subject of fœtal deformities attributable to mental impressions on the mother during pregnancy, offers an interesting field of study, which it may not be presumptuous to say has not yet been cultivated to the extent it merits. There are many theoretical questions of much significance related to it, and many deductions of great practical importance may be derived from it.

Twenty years ago it was the fashion to treat the whole subject with contempt, as being one of those popular delusions or superstitions which are unworthy the attention of a thoughtful student of nature.

This period, we may assert with confidence, has definitely past. The coincidences are too numerous and too extraordinary to leave room for skepticism. It may, indeed, be urged with justice that there are hundreds of infants born with deformities which cannot be traced to any maternal impression; and conversely, that there are hundreds of mothers frightened or shocked during pregnancy, whose infants are perfect in form. Frequently, also, the deformity bears little resemblance to that which was seen by the mother, and believed by her to be the cause of the child's condition.

To these objections it is answered in a general way that it is not pretended that all fœtal deformities arise from this cause; nor that a mental shock always produces such effects; nor that the deformity is or must be precisely like that which originated it; but only that, under circumstances and conditions not yet defined, such a sympathy exists between the mother and the child in her womb that the nutrition of the latter may be materially altered by fixed attention on the part of the former.

We all know that a sensitive person can have a pain anywhere in the body by this same process of fixed attention; actual organic changes are easily and rapidly produced; and probably the same is the case with the fœtus in utero. The analogy is strong, and the relations are parallel.

The researches of Dr. MAX RUNGE, on the

influences of alterations in the maternal blood on the fœtal organism (*Archiv für Experimental Pathologie*, Bd. x, s. 324), show in a striking manner how the nutrition of the fœtus is effected by alterations in the blood-pressure, more, even, than by alterations in the constituents of the blood, and that the processes of its growth are, therefore, more dependent upon nervous than alimentary conditions.

The subject has been revived in some of the English societies of late, and various cases reported, which appear to owe their deformities to mental impressions. Thus, at one of the meetings of the Obstetrical Society of London, Dr. Heywood Smith showed photographs of a young woman, aged twenty-eight, whose profile showed a remarkable concavity of the face, ending in a prominent under jaw. The mother had been frightened by a monkey, about the fourth month of gestation. He remarked that among animals it was at the moment of conception that the mother was supposed to receive an impression, while in women a maternal impression was often referred to the third or fourth month.

Dr. Braithwaite, however, said that he had seen a puppy having a bifid and flattened forefoot, the owner of which said that during the mother's pregnancy a stone had fallen upon the foot, and crushed it similarly to the flattened foot described.

Another case was lately laid before the Dublin Obstetrical Society, by Dr. Purefoy, in which, in the opinion of some members, the connection of the deformity with its supposed mental cause was more intimate and marked than in almost any on record. It merits, therefore, quotation :—

The infant possessed the following peculiarities: The right ear, or, to speak more technically, auricle, was altogether wanting, nor was there even a depression in the spot usually occupied by it. The right eye was also entirely absent, the position of the orbit being indicated merely by a slight depression, while on the left side the orbit appeared to contain an eyeball, completely concealed, however, by the eyelids, which were intimately united along the whole line of the palpebral commissure. The trunk and genitals were those of a large, well-made, male infant, but the limbs presented the following peculiarities: On the right side the arm and forearm were absent, but from the head of the scapula there hung, suspended by skin only, an appendage which appeared to be an abortive hand. The left upper extremity was normal in size and shape, but the fingers were united by a web of skin extending between each. The lower extremities presented no peculiarity except a similar webbed structure extending between the toes, and this was present on both feet.

When she was three or four months pregnant, a cow belonging to her husband gave birth to a calf which wanted the right ear, the right eye, and both forelegs. This extraordinary object was watched by her with great assiduity, and she superintended its feeding and endeavored to rear it. It lived for several months; and the occurrence is supposed to account for the extraordinary object of which she was herself afterwards delivered. It was born alive, but only survived a few hours. Its head was thickly covered with black hair. On the right side there was nothing at all to indicate the position of the ear.

If now the doctrine of materno-fœtal symmetry could be established, and its general laws defined, why could it not be made a most useful branch of ante-natal education? If ugly and disgusting objects can be made to produce such lasting impressions, why not, on the other hand, cannot beautiful and symmetrical ones be employed to insure perfectly formed infants?

We are aware that the idea is not a novel one; it is, indeed, centuries old, and there are more than a few instances in which it is alleged to have been successfully put into practice. Necessarily, however, this was done in an empirical manner only, and what we want is such a scientific knowledge of the laws of this physiological relation that we can apply them with a reasonable certainty of obtaining their good results and counteracting their injurious operations.

Notes and Comments.

Chronic Nicotine Poisoning.

In the *Revue des Sciences Médicales*, we find the two following observations of nicotism, taken from the *Archiv für Psychiatrie*:—

The patient in the first case, which terminated fatally, commenced to suffer from rachidian pains in 1876; they were of extreme violence and radiated toward the thighs. There was a sensation of muscular rigidity, with tremors, in the lower limbs, causing difficulty in walking. These troubles disappeared for a few weeks, galvanic currents being used, but the pains in the back soon returned, and the patient had an appearance of general suffering.

Notwithstanding the physician's strict prohibition, he continued to use large quantities of tobacco, and the following summer complained of a sensation of violent constriction about the head, with vertigo.

He was troubled with palpitations of the heart, which came on by access, waking him from his sleep; there was considerable præcordial anxiety and acute pain behind the sternum, during the access. There was nothing on auscultation but marked feebleness of the heart sounds.

The patient soon commenced to lose appetite and suffer from gastric troubles.

He was placed in an asylum, but he soon managed to smuggle in cigars, which he smoked during the night. Progress was rapidly downward, thoracic pains were felt, he was completely spent, and was seized with tremors on the slightest effort; for nine months he was completely impotent; the urinary secretion was normal. He soon died, quietly, without convulsions; nothing was found at the autopsy except very pronounced anæmia of the nervous centres.

The second, a stout, vigorous man, commenced to smoke from eight to ten strong cigars per diem.

He soon became remarkably nervous; there was great hyperæsthesia of hearing, in particular; soon he began to suffer from a feeling of constriction about the head, rachidian pains, tremors while walking or when he attempted to write.

These symptoms continued for a period, when the patient had a sudden attack of angina pectoris; after this he was induced to give up smoking, and the symptoms gradually disappeared.

The symptoms in both cases strikingly resemble each other, and conform exactly with the tableau of nicotism. These cases may, then, in certain difficult cases, give a clue to the etiology of morbid troubles of the same nature.

Transmission of Favus from Animals.

M. Megnin presented to the Soc. de Biologie, (*Progrès Médical*, January, 1881), a mouse having the head and body almost completely covered with the crusts of favus.

This mouse was found in a leather shop where, about a year previously, the first mice affected in this way had been remarked: the malady soon spread, and many of the animals were found wandering about, unable to return to their holes, being rendered blind and deaf by the crusts which covered their eyes and filled up the external auditory meatus.

This is the third example of favus in mice, the first being reported by Dr. Draper, of New York, who also observed its transmission to a cat and to some children accustomed to play with the animal.

The second case was reported by M. Tripier (Soc. Méd. de Lyon, Aug. 12th, 1867), and he succeeded in inoculating himself therewith.

Favus has also been observed in rabbits, and M. Jacquettant has observed its transmission from two children to a cat they were in the habit of fondling.

M. Saint Cyr (*Receuil Veterinaire*, 1869) has observed its transmission from cats to children, and has also, like M. Trasbot, seen it in the dog. Dr. Williams (Prin. and Practice of Veter. Surgery) has observed it in a large number of cattle and horses occupying a stable frequented by a cat affected with the disease.

In concluding, M. Megnin states that fifteen men in one battery of artillery suddenly presented numerous rings of herpes circinatus on the face. It was found, on investigation, that these men had, during a period of chilly weather, added the horse blankets to their bed covering, and that many of the horses were affected with tinea tonsurans. They were treated with ol. cadini, and with very good results.

Diphtheria and its Treatment.

M. Constantin Paul ends his review of the methods of the treatment of diphtheria brought before the Societé de Thérapeutique during the year 1881, in the following terms:—

"Diphtheria and diphtheritic poisoning still remain one of the preoccupations of therapeutics. This year, like the preceding, the results of many new experiments undertaken by members of the Society have been laid before you.

"First, the treatment of the diphtheritic patches by the bromide of potash, by M. Peyraud. M. Cadet de Gassicourt, who repeated conscientiously the treatment of our colleague, has shown, in a very interesting report, that bromide of potassium does not constitute, any more than chlorate of potash, or cubebs, a medication sufficiently efficacious to warrant the belief that we are at last able to control this scourge which has proven so redoubtable for young children and those who nurse them.

"The same must be said of the treatment of M. Brame, cauterization with the iodide of silver; of that proposed by M. Perati, cauterization with carbolic acid and camphor; of that of M. Bergeron, with fluorhydric acid, which had as

advantage, that it might be applied almost at distance, without demanding the docility of the child, so difficult to obtain for applications to the throat. Will we be more fortunate with pure carbolic acid, which has been recently proposed by M. Bournonville?

"It is necessary to say this year, as we concluded last year, that the best treatment in diphtheria is to sustain the forces of the patient by stimulants, particularly alcoholic stimulants; to disembarrass the throat of false membranes by removing them mechanically, when possible; and to perform tracheotomy, in case of obstruction, if the strength of the subject permits.

"Chlorate of potash, cubebs, carbolic acid, camphor, fluorhydric acid, lime water, and tartaric acid, are of use in diphtheria without toxic symptoms, but are insufficient remedies."

Treatment of Movable Bodies in the Knee-Joint.

The *Concours Médical* informs us that Mr. Ganjot lately read a paper on this subject, in which he states that the extraction of foreign articular bodies may be practiced without much danger. It should, however, only be undertaken when warranted by the severity of the functional troubles, and the insufficiency of all palliative means. Extraction by means of an open cut is preferable to the subcutaneous process, because it is easier and more certain in its result, without being any more dangerous, if performed while observing all proper precautions, either with or without the aid of Lister's dressings.

Hygienic Treatment of Biliary Calculi.

In the *Bulletin de Thérapeutique*, Prof. Bouchardat gives the following rules: 1st, abstain from bread, eggs, nitrogenized aliments in excess, tomatoes, strong liquors, from fish, oysters, etc., from old cheese. Instead of bread make use of potatoes, and take ordinary vegetables containing potash in preference to those containing soda. Make an indirect alkaline medication by using fruits containing malates and citrates. 2d, keep the bowels in a soluble condition, taking a tablespoonful of tartrate of potash or soda, or of sulphate of soda in lemonade or orangeade, each morning. 3d, moderate exercise. 4th, render the cutaneous secretions more active by frictions, etc. One to three baths weekly, containing—

℞. Potass. carb., ℥ iij
Ol. lavand., ℥ ss
Tr. benzoin, ℥ j,

followed by prolonged frictions and massage. 5th. (*a*) In order to induce expulsion of the calculi, small doses of spts. terebinth, and of ether in capsules, either at meals or preferably, between meals. *b*. To prevent the formation of calculi, for ten days, before the morning and evening meal, a pill containing one decigram (gr. iss) of tartrate of potash and lithia; during the ten days following—

℞. Potass. acetat., ℥ v
Syr. sarsæ comp., ℥ xij. M.

Tablespoonful morning and evening.

Then, for ten days, a quart of water daily, containing ten grams (℥ iiss) of Rochelle salts.

Rose-flavored Sulphuric Lemonade.

The *Concours de Médical*, gives the following formula for its preparation and general application:—

℞. Red rose petals, 20 grams (℥ v)
Boiling water, 1000 " (Oij)
Dilute sulphuric acid, 4 " (f. ℥ j)
Sugar, 100 " (℥ xxv).

The rose petals are to be infused for an hour in the boiling water, after which strain, and add the dilute and sugar.

This lemonade may be used in all cases where acids are recommended. In *fevers*, in *hemorrhages* without circulatory troubles, or when attended by inflammation or fever.

It may be given in *anginæ* of a serious type, or in *diphtheritic angina*. In this last disease it acts on the lesions in the same way as an acid, by modifying the affected surfaces, and readily takes the place of a *detersive* gargle, which children generally are unable to use.

It is well indicated in *scurvy*, and in the *putrid* and *hemorrhagic* stages of *typhoid fever* and *variola*. It may be taken cold or even iced. Small quantities should be taken at a time, and at reasonable intervals, so as not to irritate the stomach. About a Madeira glassful every three or four hours is a quantity which will suit almost all cases.

The Treatment of Malignant Pustule.

At a meeting of the "Société de Chirurgie" Mr. Boisset alluded to the fact that the treatment of malignant pustule and malignant œdema by intestinal injections of iodine, is at present in great vogue, and expressed his regret at not receiving the credit to which he believes himself entitled in connection therewith. The fact is, that ever since 1855 he has advocated the use of iodine in the various forms of anthrax; he recommends it for its anti-virulent qualities, not

only in charbon, but also in farcy; iodine is far more efficient than the actual cautery, because in the shape of tincture it penetrates within the tissues, and reaches far deeper; therefore, when injected in the tissues they are so energetically acted upon that a sort of barrier is thrown around the evil, and its further progress is permanently checked. The effects of the iodine are greater in proportion to the concentration of the tincture.

Trichinæ in Meats.

The *Progrès Médical* reports that Mr. Pouchet has made experiments in his laboratory, on three rats, which he fed on both salted and smoked trichinous meats. On dissecting those animals, he found no trichinæ cysts in their muscles, but great quantities in the intestinal cavity, showing no signs of having been acted on. He therefore concluded that those meats were not dangerous.

Mr. Bert says that pickling, when recent, does not kill trichinæ, but after a time they die of their own accord in salted meats, in the same way as they die in the human muscles. How long does it take to bring about this result? From experiments made in Denmark, it would seem that from one to three or four months are necessary. The fact is, this point is still in darkness, and it is the more to be regretted that there exists no reliable method by which it is possible to ascertain whether trichinæ contained in meats are alive or dead.

Sulphate of Copper in Croup.

M. Thibon, in the *Lancette Belge*, becomes quite enthusiastic over the therapeutic effects of this medicament. He considers it to be not only a very efficient emetic, but also a powerful parasiticide, and therefore of especial value in croup, first causing the expulsion of the false membranes and then preventing their reproduction, through its destructive action on the vegetable organisms.

Practically, he asserts that this medicament has given him favorable results in very desperate cases; it should be given in sufficient doses; children of two years of age have taken over one gram (gr. xv) in 24 hours without any toxic effects. M. Thibon employs the following potion:

℞.	Cupri. sulph.,	gr. viij
	Aquæ,	℥ ij. M.

A teaspoonful should be given every ten minutes until vomiting is induced; afterwards the same dose may be repeated every hour, and later, every second hour.

Accidents Attending the Internal Use of Iodoform

The "*Deutsche Zeitschrift*" reports that Oberlænder, in Dresden, met with two cases of syphilitic women who experienced very serious accidents from the internal use of iodoform. The first, in the space of eighty days, had taken 42 grains (f. ℥ xss), in the form of pills, of 5 centigrams each. She experienced weakness, giddiness, diplopia, and coma, followed by violent excitement, by headache, and continued loquacious delirium, and, finally, by real paralytic weakness of the limbs. These symptoms continued for two weeks, and then disappeared. The other was overtaken by similar symptoms, after seven days of iodoform. She fell into a somnolency, which continued for five days, and was followed by giddiness, and a paralytic weakness of the limbs, which lasted several weeks.

Nerve Stretching in Neuralgias.

The "*Progrès Médical*" reports that in October last Mr. Quinquand had recourse to stretching of the frontal nerve, in a case of supra-orbital neuralgia; in November, one of his colleagues, a surgeon, performed the same operation for an epileptiform facial neuralgia, and also for a supra-orbital neuralgia. The first and third operations were followed by permanent cure. The second has not been attended with so favorable a result. In the two cases cured, anæsthesia had immediately been total and complete, and continues to this day; while in the epileptiform neuralgia anæsthesia lasted only a couple of hours. The inference to be drawn from this, and what appears as our sole operative guidance in nerve stretching, is that anæsthesia must become persistent in order to insure a cure. What is it, then, that takes place within the tissues? In the absence of any histological examination, it was supposed that a dynamic action took place. Mr. Quinquand has elucidated this question by means of experiments made upon animals. He has observed that when the stretching is insufficient, that is, when attended by only temporary anæsthesia, the nerve presents no perceptible lesion. On the contrary, when anæsthesia is persistent, he finds that a number of nerve tubes give evidence of secondary degeneracy; in some, the myelin appears granular and divided; in others no trace of it is found; while others again are intact. He, therefore, concludes that the operation should be pushed so as to bring on complete anæsthesia, and that the result is not due to a dynamic effect, but to an anatomical lesion.

Treatment of Chronic Ulcer of the Stomach.

The treatment of chronic gastric ulcer by injection of water and other fluids into that organ, or rather complete washing out of the stomach (lavage de l'estomac), has not attracted the attention which the therapeutic results obtained would seem to merit.

A very interesting case is recorded in a recent number of the *Progrès Médicale* (April 2d). A patient fallen into a very cachectic condition was admitted as incurable, into M. Debove's service at Bicêtre. He recounted that ten years previously, during the war, he once found himself in great danger and lost consciousness; when he came to himself he vomited a considerable quantity of blood, and this has happened five or six times since then; during the intervals he vomited bilious and glairy matters, and these symptoms were accompanied by intense pain over the stomach. When he entered the service there was absolute intolerance of the stomach; he vomited even a few spoonfuls of milk that he attempted to take; he was reduced to the last stage of emaciation, could hardly support himself upon his limbs, and death seemed imminent.

In presence of such a desperate condition, M. Debove determined to make use of the process of Faucher for washing out the stomach. A long soft tube in caoutchouc was employed; there was no difficulty in introducing it into the stomach, and no danger of doing any injury if it was introduced too deeply; a simple glass tunnel was adapted to it externally, and in this way eight quarts of ordinary water and two quarts of Vichy water were daily allowed to circulate in the organ. After three or four days, the patient was able to introduce the tube and perform the treatment himself; at the same time a milk diet was ordered, with 200 grams of raw meat daily, and concentrated meat juice or essence, prepared by five or six hours' coction in a hermetically closed vessel.

The treatment has now been continued for six weeks, and with very remarkable results. Pain has completely disappeared; vomiting has ceased, and the patient is much stronger. The patient is able actually to digest vegetables and salad but his augmentation in weight demonstrates best the results of the treatment.

The first day of treatment he weighed 125 pounds, seven days later 132 pounds, and for four weeks following he gained 100 grams, three and (one-third ounces) per diem.

The results are then very remarkable, and as can be seen, the treatment was executed with facility.

Pesudo-Caverns in the Lungs.

In the *Revue de Thérapeutique Méd. Chirurg.* attention is called to the fact that frequently all the stethoscopic signs of an excavation are present at the apex of the lung when in reality there is no cavity.

This happens in pleuritis; the liquid compresses this part of the lung, and the sounds generated in the trachea and bronchial tubes are transmitted through the compressed pulmonary tissue.

The course of the disease clears up the diagnosis; the effusion being absorbed, the signs of a cavity disappear; if they persist, there is probably a cavern.

In certain cases, the lung being in a state of atelectasis, with concomitant bronchitis, humid, sub-crepitant râles are transmitted through the condensed tissue, and give the idea that the gurgling râles of phthisis (gargouillement) are present.

Treatment of Infantile Diarrhœa.

A fact not sufficiently considered, remarks a writer in a recent number of the *Revue de Thérapeutique Méd. Chirurg.*, is that the treatment of intestinal catarrh in infants should be persevered in until a complete cure be obtained; the gastro-intestinal functions should be completely re-established before ceasing treatment. The proper therapeutic measures consist in the employment of bismuth and laudanum, and without this last medicament it is very difficult to have complete cure, in infantile diarrhœa. The following potion may be given, a teaspoonful at a time, in the course of twenty-four hours:—

℞.	Bismuth. subnit.,	ʒ ij	
	Tr. opii,	♏ ij	
	Mucilag acac.,	ʒ iv.	M.

An enema of starch should be administered morning and evening. The little patient should be kept in bed; alimentation should consist of milk, panada, etc. This treatment should be continued for eight days, then the doses may be diminished, but the progress of the case should receive careful attention.

Sulpho-cresylate of Soda.

This is a new chemical agent discovered by Mr. Rabuteau in the mother liquors resulting from the preparation of sulpho-phenate of soda. It is a white salt, has first a saline, then a sweet taste, and its properties are analogous with those of sulpho-phenate of soda.

Correspondence.

Doctors' Mistakes and Blunders.

Ed. Med. and Surg. Reporter.—

Seeing that only so few of your host of subscribers were willing to throw their colors to the breeze and come up like true Spartans and give us a piece of a column now and then, on that very interesting subject, "Doctors' Blunders," I hasten to contribute my mite, deeming it a duty of every physician, which he owes his medical brethren, particularly the novices, to publish his failures as well as his successes. But possibly all who ever sinned have confessed, have been heard from in the column of "Blunders;" nevertheless my conviction is, if every case of the kind came to light, where the physician saved his neck, so to speak, by adroitly covering in his tracks, they would fill a book larger than Webster's Dictionary.

Why does not some ambitious book writer come to the front with a treatise on this subject? It would outstrip any work in the book market, in the way of sales, and the author would immortalize his name besides.

Of course its sales should be limited to the medical fraternity, else it might place us in a bad light. No doubt it would at first seem a curiosity; but then we must move early, with our eyes wide open, to be up with the enterprise of the ninteeenth century.

Let us have the cases of pneumonia and other diseases which have been strangled by paralyzing doses of poison—veratrum, aconite, belladonna, digitalis, strychnia and morphia! Those which have come to an untimely end by the injudicious use of the lancet and leech; those cases wherein we are told that the way to strengthen is to weaken.

Let us hear from those health officers who are sending cases of scarlatina, measles, chicken pox and nettle rash to the pest-house, that they may be treated for smallpox.

A case was reported in this city some time since, of a youth who was spirited away from his father's comfortable dwelling, amid fumes of burning sulphur, in a closed van, to the Island Hospital. There the doctors declared that he had measles. He was detained long enough to absorb sufficient of the variolous contagion to infect a whole neighborhood, however. Thousands of mistakes (*errors in diagnosis?*) might be found.

I shall delay no longer with preliminaries, but launch out and give the history of one among the many of my own. About the middle of the summer of 1880, a young man with his wife came to my office for the purpose of securing my services when she would be confined, saying that she expected it would be in one month from that time. She was very anxious to learn as to whether I could be found in at night or not, and so on. Shortly they both left. The month passed, another came and went, but no Mr. B. called. Alas! no call to Mrs. B., I said to myself; ten dollars out. My patient could certainly not have held out so long; and to confirm my suspicions I soon met Mr. B. in the street, but, to avoid me, he crossed to another corner. But, thanks to my lucky planet, bang! goes the gong, next evening, at midnight. I raise the window. Mr. B. is there, and in an anxious and hurried voice calls me to go at once and see his wife, who is *sick*, and to bring such things as I might need. Well, it did not take long for me to get inside of my clothes. Let us see what I need. Ergot, pernitrate of iron, iodine, opium, tape, and a good, stiff-backed syringe. Now, with a copy of Handy Andy crammed into my pocket, away I ran, soon reaching the sick chamber, nearly out of breath, fearing that I might be there in time to be too late. I made all possible haste. Off with my hat and coat, and into the sick chamber I went. Mrs. B. had so much pain that she could not answer me, whether the pain was in her back or bowels, or, in fact, anything. Not being able to make her yield to an examination, and the pains ceasing entirely—as the obstetric teacher tells us, when the doctor arrives, they often do—I made her swallow a good full drachm of the fld. extract of ergot (Squibb's), quickly followed by a cup of ginger tea. Now, says I, comfortably stretching myself in a large, soft, rocking chair, I will read a while. O Doctor! she cries, and up I jumped: the pain, she said, would kill her; the medicine is doing the work, I said. She turned on her side, declaring that I knew nothing; a whim, too trifling to notice. I told her she would think differently by and by. I made my way, as well as I could, up to the mons veneris. Vagina moist; natural heat. The os uteri patulous, readily admitting the finger.

The presentation and bag of waters are what I am after. As I kept my finger there for a moment, I rapidly revolved in my mind the different presentations, and possible monsters, though sharply eyed by the nurse and savagely stared at by the husband, from another room. Still I could not forget what I once heard the late lamented Dr. Chas. A. Budd say, in his lectures, "That sometimes one could not tell, in making a vaginal examination, whether he was afoot or on horseback." While in this momentary quandary, I heard something that made my hair stand, from the very roots, and my knees suddenly weaken—my heart seemed packed into my trachea—the cry of an infant in a cradle, covered with a canopy. There! get out, you quack, shouted the patient, the lying in? I said you knew nothing. The husband swore he would prosecute, and I got out with my life, but no fee.

New York City. Thos. H. Manley, M.D.

The Concentration Theory of Trance.

Ed. Med. and Surg. Reporter:—

In your last issue you say, editorially, that a theory of the phenomena of trance is the great need.

That need was supplied nearly five years ago, by my *concentration theory*, which was first publicly announced at a meeting of the New York Medico-Legal Society, in the Autumn of 1876, and subsequently published in my work, "The Scientific Basis of Delusions," which work was, if I remember rightly, strongly commended in

your journal. Prof. Präger, of Jena, in his very latest paper on this subject, which he has just sent me, states my concentration theory and gives me credit for it. His attention was first called to it by my remarks on the subject at the last meeting of the British Medical Association, in Cambridge.

Although my theory attracted attention only among a very few experts in psychology, yet by these experts it was received, in the main, with approval, though not always with intelligence. Last summer, while in Germany, I purchased the pamphlet of Schneider to which you refer, and saw at once that he was in the direction of my theory, and I so stated in a lecture on induced or mesmeric trance, before the New York Academy of Sciences, in January of the present year. I do not think that Schneider had ever read my paper, although it was several times republished in Europe.

Heidenhain's theory of suspension of the higher centres with activity of the lower, is also in the line of my concentration theory, so far as it goes, but does not account for the phenomena, and is, therefore, not pushed or pressed by him or by others to any great extent.

My theory is psychological, not physiological or anatomical; it is based on mind, not on the brain; and, briefly stated, is concentration of nervous activity in one direction, with suspension in other directions. The time has not come, perhaps may never come, when a theory of trance can be based on the anatomy or physiology of the brain.

In my work I did more than suggest this concentration theory; I proved it, by showing that it accounted for and harmonized all the phenomena of trance in all its varieties; and, yet further, I stated that if any new phenomena of trance should be discovered, this concentration theory would account for them all, up to a certain point, at least. This prediction has been fulfilled; for during the past few months I have made a number of discoveries of detail, all of which are explained by this theory. These new facts will be brought out in my work on trance, now in preparation. Some of these later experiments were made public at a meeting of the Medico Legal Society, last week.

Among these new facts may be mentioned the absolute demonstration of blindness in one eye, of abolition of the sense of vertigo, hemianæsthesia and hyperæsthesia, and absolute deafness; color-blindness I have also demonstrated, as Cohn had done before, though not, I think, by the same method. I have also confirmed the old claim that a trance subject may, in rare instances, see, with thoroughly bandaged eyes; the tests were made with playing cards, all the six sources of error being eliminated. This last experiment was confirmed and repeated by Dr. C. L. Dana and Dr. W. G. Morton, of this city; and is the easiest to verify of all the experiments that can be made with trance subjects.

But, as you truly say, what we want is the explanation of these phenomena; while some of these detailed experiments are new—but a few weeks or days old—others have been known or claimed for centuries.

My claim for the concentration theory is, and from the first has been, absolute and uncompromising; that it accounts for and unifies all the phenomena of the varieties and sub-varieties of trance, by whatever names known or described, and brings order out of confusion in this whole subject, doing for it what the theory of gravity does for the movements of the heavenly bodies, or the wave theory for the phenomena of light. GEORGE M. BEARD, M.D.

161 *Madison Ave., N. Y., May 9th.*

Feeding of Infants.

ED. MED. AND SURG. REPORTER:—

Reading, in the MEDICAL AND SURGICAL REPORTER, April 30th, page 490, "Constitution of Human Milk," by F. Hoppe Seyler. leads me to offer my substitute for human milk, which may, for aught I know, not be new to some of your readers; to me it did not come from reading, but from a determined effort to prevent a bottle-fed baby from dying of inanition. The history of my little patient is the usual one of vomited and defecated, undigested curds, with emaciation and pain, in spite of pepsin, subnit. bismuth, lime water, etc.

I ordered milk, one part, the whites of eggs, well beaten, two parts, warm water, one part. Place in the nursing bottle, and allow only at regular intervals of three hours. Continued pepsine. Allowed no sugar, believing that cane sugar in the stomach of the infant with undeveloped salivary glands is incapable of behaving like sugar of milk.

The result was all that could be desired, the patient improved at once and soon became as plump and perfectly nourished as any breast-fed baby could be. This method of feeding only occurred to me last summer, and the opportunities for verifying its value were not numerous, but in the dozen cases tried the results were eminently satisfactory. I got rid of a large amount of the caseine and substituted fresh albumen in its place.

Greeley, Col. G. LAW, M D.

Treatment of Measles.

ED. MED. AND SURG. REPORTER:—

Having seen *quite* a number of cases of measles in the past eight weeks, both mild and severe, complicated and uncomplicated, I have been induced to say a word in regard to its treatment.

As we all know, when this malady affects a patient, it goes naturally through its several stages without any *special treatment*, except that of "Old Times" ("Saffron Tea, etc.") There is generally a diarrhœa, about the fourth or fifth day, which should be allowed to go unarrested, for the reason that it is seemingly an effort on the part of "Nature" to rid the mucous membranes of both the stomach and bowels of the infectious matter accumulated therein; should, however, this state of *affairs* continue to such an extent as to affect the strength of the patient, we might give relief by medication.

The *headache* in the early stages of the disease is quite severe, and in the same way could be re-

lieved, for it, as a rule, accompanies the vomiting and diarrhœa.

The simple treatment I offer for ordinary cases of rubeola, or rubeola simplex, is the following:—

℞. Morphiæ sulph., gr. j
Liq. calcis,
Aq. menth, āā ℥j. M.
Ft. solution.

Sig.—One to two teaspoonfuls every hour, according to age, until relieved.

Any form of opium can be used, according to age of patient, and the time prolonged or shortened, according to choice of physician.

Having seen a case a few hours ago, which presented symptoms of dysentery, I ordered the following prescription:—

℞. Pulv. opii, gr. ij
Bismuth subnit., ℈j
Salicin, gr. vj. M.
Excipiente, q. s. ut ft. pil. No. iv.

Sig.—One pill every two hours, until bowels are quiet.

I will report from time to time, any case that might be worthy of reporting. This disease I report because there are many younger members of the profession who might be induced to use simple remedies, and have good success, whereas they might use *violent medicines*, and do more harm than *good*. W. B. Powell, M.D.

Natchitoches, La.

News and Miscellany.

Medical Society of Pennsylvania—Thirty-Second Annual Session.

The Society met at Lancaster, in Fulton Hall, Wednesday, May 11th. At 11 o'clock, the President, Dr. J. T. Carpenter, of Schuylkill county, called the meeting to order, and the exercises were opened with prayer by Rev. J. Y. Mitchell, D.D.

The reading of the list of delegates was dispensed with, as all the delegates had not registered their names. Dr. Henry Carpenter, of Lancaster, Chairman of the Committee of Arrangements, welcomed the delegates in the following words:—

Gentlemen—Delegates to the Meeting of the Medical Society of the State of Pennsylvania:

It is my very pleasing duty—on behalf of the Lancaster County Medical Society—to tender to you a cordial, hearty welcome to this, our ancient city, the birthplace of your Association thirty-three years ago. This Association was organized in this city, and alas! how sad to contemplate how few of the cherished old familiar faces of that day are present here now. We miss the cordial, friendly grasp, and genial, pleasant faces of Hume, Muhlenberg, Burrowes, Hays, Emerson, Worthington, Coates, Norris, Parrish, Hiester, Jackson, Mutter, Duffield, Carpenter (of Pottsville), Kerfoot, Carson, Richards, Maybury, Raub, Huston, Condie, and scores of others who "have passed the bourne," whom we were formerly so delighted to meet, and unto whose voices, pregnant with words of wisdom and instruction, we were so pleased to hearken. But in the language of the poet, "*Mors Janua vitæ*"—

> "Death is the gate to life eternal—
> The entrance to immortal life."

So that we may console ourselves by the reflection that "our loss has been their gain."

We may claim for Lancaster that it is the largest, as well as the oldest inland city of our rapidly-growing country. It was laid out as a borough by James Hamilton, a landed proprietor, getting title from the English crown, in the year 1728; and the adjoining territory erected into a county in 1729, one year subsequently. The city contains a population bordering upon 30,000 inhabitants, while the surrounding country is a little empire, comprising an area of over 620,000 acres, or about 969 square miles, and peopled by about 150,000 inhabitants. It is eminently an agricultural district; its great fertility and productiveness having long since gained for it the enviable name of the "Garden of America." It has been long famous for its big Conestoga horses, great crops of wheat, corn, and latterly of tobacco, industrious and frugal inhabitants, and last, but by no means least, its large number of pretty girls; which condition of things may serve to explain to you the fact that all of our physicians are well-to-do married men (I myself have enjoyed that felicity three several times), all surrounded by the bounties, as well as the cares and consequent responsibilities of the situation, which facts you can prove by calling upon them, at their homes, where you will find the latch-string hanging freely out, and all most delighted to meet and welcome you. But I will not longer tire your patience with these crude and hastily conceived sentiments, but in their name, and that of their families, wish you a hearty, sincere and cordial welcome to their homes.

On motion of Dr. S. T. Davis, of Lancaster, all physicians in good standing in neighboring societies were given the privileges of the floor and the courtesies of the meeting.

Dr. E. P. Townsend, of Beverly, N. J., a representative from the State Medical Society of New Jersey, being present, was received and invited to the platform.

Dr. Townsend replied as follows:—

Mr. President and Gentlemen:—It gives me great pleasure to meet with you again, to represent the State Medical Society of New Jersey, before this distinguished body. The State Medical Society of New Jersey believes in the policy of Inter-State delegations, and regularly appoints delegates to adjoining State Societies

Having had the pleasure of representing her at your last annual meeting, at Altoona, I carefully watched your proceedings and tried to report to my Society the salient features of your meeting. One of the most notable of these, was your resolution, formerly passed, and last year so earnestly advocated by Dr. Traill Green, requiring a preparatory examination of all applicants for the study of medicine, as to moral and mental qualification. This resolution was reported to the New Jersey Society, and I am happy to say, similar regulations were adopted,

and made incumbent upon the county societies to fulfill. The old centenarian is proud to copy all from her younger sister organization that may tend to the elevation of our beloved profession.

I shall watch the working of your action of last year, on this subject, with considerable interest. In conclusion, gentlemen, I cordially extend, not only to the delegates whom I hope you will appoint, but to each and every member of this honorable and distinguished body, an invitation to attend the one hundred and fourteenth annual session of the New Jersey State Medical Society, to be held at Long Branch, on the fourth Tuesday of this month.

Dr. Henry Carpenter read the programme as arranged for the session. On motion it was adopted.

Dr. O. H. Allis, of Philadelphia, Corresponding Secretary, reported but one item, the formation of a new medical society in one of the counties. He also presented his report on the library, with a set of rules for its government.

At the meeting of 1880, the following resolution was adopted:—

Resolved, That the Philadelphia County Medical Society be constituted the custodian of the publications of the Pennsylvania State Medical Society and of the transactions of such other State medical societies as shall exchange with it, until the Pennsylvania State Medical Society shall make other provision for the same.

Resolved, That the Publication Committee shall be constituted a library committee, to report at the next meeting of this Society the rules and necessities of such a library.

In pursuance of these resolutions the following rules were offered:—

Name.—The name of the Library shall be The Library of the Pennsylvania State Medical Society.

Contents of Library.—The Library shall consist of the Publications of the State Medical Society; the Exchanges with other State Medical Socities and medical organizations as may be effected and deemed judicious by the officers of the Library.

Officers of the Library.—The officers of the Library shall consist of the Committee of Publication of the Pennsylvania State Medical Society, together with the Librarian of the Philadelphia County Medical Society.

Duties of the Officers.—They shall appoint one of the members of the Publication Committee as the Correspondent of the Library, whose duty it shall be to solicit suitable additions to the Library, and to make an annual report of the condition and progess of the Library to the State Medical Society. They shall meet at the call of the correspondent. They shall appoint the necessary officers and make the necessary rules for the promoting of the objects of the Library.

RULES OF THE LIBRARY.

1. The Librarian of the Philadelphia County Medical Society shall be the Librarian of the Library of the Pennsylvania State Medical Society.

2. The Library shall be accessible to the members of County Medical Societies of the State of Pennsylvania.

3. The books of this Library shall not be taken from the Library Building. They shall be for reference, not for circulation.

On motion, the report was accepted and the rules adopted.

Dr. Traill Green presented a bill for committee expenses, which was ordered paid.

Dr. R. S. Sutton, of Pittsburgh, offered the following, which provoked some discussion, viz:

SECTION 2, Article III, of the Constitution shall be so amended as to read as follows:—

Every member of a county medical society in Pennsylvania shall, so long as he is in good standing, be a member of the State Medical Society, and a delegate to its annual sessions.

Under the law, it laid over for one year.

On motion of Dr. S. T. Davis, it was agreed that in future each delegation to a sister society, or the American Medical Association, shall organize and appoint a chairman, who shall report at next meeting of this body.

Dr. Varian reported that, as a delegate to the Connecticut State Society, he had been unable to find that body.

On motion, a recess of twenty minutes was allowed for the delegation from each county society to select its representation on the nominating committee.

After which, the society adjourned until 2 P. M.

(To be continued.)

The Association of Medical Editors

Met at Exchange Hotel, Richmond, on Monday evening, May 2d, at 8½ o'clock. In the absence of Dr. J. F. Shrady, President, Dr. Octerlony was called to the chair, Dr. D. S. Reynolds, Secretary.

Dr. Shrady's address was read by Dr. Carpenter, and on motion it was ordered that the same be printed.

The Committee on Necrology (Drs. Dunstar, Cole, and Edwards), was appointed. The Committee reported the death of Drs. Davis and Cowling during the past year, and requested indulgence for the preparation of their report on memoirs, which was granted.

The Committee on Nominations of Officers for the ensuing year reported as follows: President, Dr. Landon B. Edwards, Richmond, Va.; Vice President, Dr. Ralph Walsh, Washington; Secretary, Dr. D. S. Reynolds, Louisville.

American Medical College Association.

There was quite a full attendance at the meeting of this body. The meeting was called to order by the President, Professor S. D. Gross, M.D., of Philadelphia, Professor Laertes Connor, of Detroit, acting as Secretary.

The following are the officers elected for the ensuing year:—

President.—Professor J. M. Bodine, of the Medical Department of the University of Louisville, Kentucky.

Vice President.—Professor W. T. Briggs, of Nashville, Tennessee.

Secretary and Treasurer.—Professor Laertes Connor, of Detroit, Michigan.

Secretary Connor's report shows an increase of two in the active membership of the Association since the last annual meeting. From the reports of the several colleges, made to the secretary, it appears that these institutions had conformed more universally and completely to the requirements of the Association than heretofore, and that everything pertaining to their connection with the body was entirely satisfactory.

The report of the Committee on Medical Col leges showed that sixty-four catalogues of col leges had been examined, and that only sixteen of them had failed to come up to the Association's requirements in the matter of graduation. It also appeared that twenty-two of the colleges had surpassed these requirements in one or more of the three following particulars: First, matriculation examinations; second, nine months' regular attendance; third, the three regular terms required.

The American Surgical Association.

The American Surgical Association met at the hall of the House of Delegates, Richmond, Dr. S. D. Gross, of Philadelphia, presiding, and J. R. Weist, of Indiana, secretary.

At the request of the President, Dr. Packard read the Constitution and By-Laws, which were unanimously adopted. Under this constitution, surgeons known as "specialists" are allowed to become members of the Association. Under the old constitution that class of surgeons were excluded.

Dr. Packard, the treasurer, reported that he had received $925 from members, which, with the interest ($9.25), was deposited to the credit of the Association in the Philadelphia Savings and Trust Company.

An amendment to the constitution was adopted, to the effect that all nominations for membership shall lie over until the next regular session.

The Oriental Hotel, Coney Island, New York, was selected as the place for the next annual meeting. The 13th, 14th and 15th of September was selected as the time.

The following is the list of officers of the Society:—

Samuel D. Gross, President; Drs. S. A. Dugas, 1st Vice President; James R. Wood, 2d Vice President; J. R. Weist, Recording Secretary; W. D. Briggs, Cor. Secretary; John H. Packard, Treasurer.

Council—Drs. Moses Gunn, John T. Hodgen, Hunter McGuire, J. C. Hutcheson, Samuel D. Gross, J. R. Weist, R. A. Kinloch.

Pepsin Preparations.

The pepsin preparations of William Proctor, Jr., of Philadelphia, have acquired an honorable and merited reputation with the profession. He prepares a saccharated pepsin, a pepsin fortior, and a vinum digestivum, all presenting in various strengths this active element. The pepsin fortior dissolves coagulated albumen, in the ratio of gr. j. to gr. 150. It is soluble, pure, and free from unpleasant odor. The saccharated pepsin consists of purified pepsin and milk sugar in such proportions that ten grains of the powder dissolved in a fluid ounce of the water, containing six drops of muriatic acid, will completely dissolve 120 grains of coagulated albumen in from four to six hours, when digested at the temperature of 100° to 105° Fahr. The vinum digestivum we have also employed in various cases, and can report highly satisfactory results from this as well as the other preparations mentioned.

Pharmaceutical Display.

The displays of pharmaceuticals, etc., at the meeting of the American Medical Association this year, were uncommonly rich and attractive. Among the firms giving the finest exhibits we may name Messrs. Parke, Davis & Co., Detroit; W. H. Schieffelin & Co., of New York; McKesson & Robbins, New York; John Wyeth & Brother, Philadelphia; Trommer Extract of Malt Co.; E. F. Houghton & Co. (cosmoline); John Reynders & Co. (surgical instruments); Charles T. White & Co., New York; and Jerome Kidder Manufacturing Co., New York.

Most of these exhibits were extensive and advantageously displayed. It is an indication both of good taste and business energy for firms to make them, and we trust that the Association will always favor this collateral branch of its activity.

On Vivisection.

A committee of the Medical Society of the State of New York have addressed to the officers and members of the American Society for the Prevention of Cruelty to Animals a letter, the main paragraph of which reads as follows:—

With you we earnestly desire to prevent every form of unnecessary suffering. But we would most strongly draw your attention to the radical difference between the infliction of wanton cruelty and the serious and careful use of the lower animals for the benefit of humanity and the brute creation; and we respectfully ask that the name and authority of your Society may not be employed to the injury of the medical profession and of medical science.

Medical Association of Georgia.

The Thirty-second Annual Session of the Medical Association of Georgia was held in Thomasville, on April 20th and 21st, 1881. The following are the officers for the ensuing year:—President, William F. Holt, Macon; First Vice President, Eugene Foster, Augusta; Second Vice President, T. M. McIntosh, Thomasville; Secretary, A. Sibley Campbell, Augusta; Treasurer, K. P. Moore, Forsyth. The next session will be held in Atlanta, on the third Wednesday in April (19th), 1882. Communications should be addressed to A. Sibley Campbell, *Secretary.*

The Louisville Medical News.

The publishers of the Louisville *Medical News* have secured as its editor Dr. J. W. Holland, a gentleman already known as an able chemist, an eloquent lecturer, and a graceful writer.

International Pharmaceutical Congress.

The Pharmaceutical Society of Great Britain deemed this year to be a fit opportunity for inviting the International Pharmaceutical Congress to hold a meeting about the same time as the International Medical Congress. Under date of January 1, 1881, the invitations were sent out to the various pharmaceutical bodies and to prominent pharmacists in different countries, and no doubt can be entertained that the meeting will be a success, certainly as far as will concern the presence of representative pharmacists, and it is to be hoped, likewise, in regard to the number of nationalities represented.

The Plague.

Telegrams to early in April represent the plague as very severe in certain parts of the Euphrates valley. In some houses ten out of twelve have died. All vessels from the Persian Gulf have been quarantined at various Red Sea ports. The disease is undoubtedly the genuine bubonic pest.

Personal.

Dr. W. J. Holt, an eminent physician of Montgomery, Ala., died April 27th. He was one of the young Americans who, after completing study in Paris, entered the service of the Russian Government, in the medical department, during the Crimean war.

Over 1000 Deaths from Smallpox.

During the last week 146 cases of smallpox were reported in Philadelphia, of which thirty-five were fatal. Since November last there have been very nearly 5000 cases of smallpox in the city, of which over 1000, or one in five, died.

—The Washington *Republican* states that many recent patents relate to interments.

Thus one of them provided a lock and alarm arrangement, which is intended to give notice of any interference with a grave. Among other things the scheme provides for the explosion of a bomb of dynamite, which would send the unfortunate grave robber a quarter of a mile up in the air. Another was for a patent swinging cooling board. A third was for an embalming fluid or process, and another was for an improved cooling board with a kind of coffin attachment.

OBITUARY NOTICES.

—Dr. Salvator Caro, of New York City, died April 30th, from prostration and worry, brought on, it is said, by a law-suit. Dr. Caro was a native of Sicily, Italy, where he was born Feb. 15, 1823. His parents were wealthy, and he was educated in the College of the Franciscan Friars at Trapani, and the University of Palermo. He was connected with the Civic Hospital of Palermo from 1843 until 1852, when he came to America. He resided in Elizabeth, N. J., for three years, and then settled in this city. In the lapse of twenty years he amassed a considerable fortune. Dr. Caro was a member of the County Medical Society, a highly esteemed Fellow of the New York Academy of Medicine, an active worker in the Pathological Society, and a corresponding member of the Royal Academy of Medical Sciences of Palermo. As a medical author, his memoirs on the action of bromide of potash and the sedative properties of the sulphate of quinia were highly regarded.

—Dr. Max Herzog died in N. Y. City, April 13th. He was a prominent and active member of various medical and scientific societies, among them the Medical Society of the County of New York, the New York Academy of Medicine, the Physicians' Mutual Aid Association, the Neurological Society, and the Medico-Legal Society. He was one of the founders of the new infirmary on Madison Avenue, and generally noted for the zeal and spirit with which he entered into all benevolent enterprises.

—Dr. Charles McGill, a well-known physician of Richmond, Virginia, died early in May, in the 75th year of his age. Before the war he was a resident of Hagerstown, Maryland, but he joined the South, and after the close of the war made Richmond his home.

MARRIAGES.

FINCH—MYERS.—In New York, on Thursday, April 28th, at "Chatsworth," the residence of the bride's parents, by the Revs. H. V. S. and A. E. Myers, Edwin W. Finch, M.D., and Emma W., daughter of James Myers.

FITCH—AKERMAN.—May 5th, at Trinity Chapel, New York, by the Rev. C. T. Olmsted, Simon Fitch, M.D., of Halifax, Nova Scotia, and Elizabeth J. Akerman, daughter of the late William Akerman, Esq., of Portland, Me.

GREEN—CARPENTER.—On April 21st, 1881, at St. Peter's P. E. Church, by the Rev. Thomas F. Davies, D. D., Dr. William L. Green and Miss Mary Frances Carpenter, daughter of Frances Carpenter, both of this city.

HARWOOD—SMITH.—At the Church of the Holy Trinity, N. Y. City, on Thursday evening, April 28th, 1881, by Rev. Stephen H. Tyng, Edward Coke Harwood, M. D., and Ida Acheson Smith, daughter of Wm. Smith, Esq., of N. Y. City.

PRICE—WILEY.—At Bridesburg, Philadelphia, April 14th, by Rev. A. A. Dinsmore, Thomas H. Price, M.D., of Morgantown, West Va., and Georgie Wiley, of Philadelphia.

READ—WHITNEY.—April 28th, 1881, at Spruce Street Baptist Church, by the Rev. Wm. S. Roberts, William Pratt Read, M.D., and Miss Kate R. Whitney, both of Philadelphia.

DEATHS.

CLARK.—In this city, on the 29th ultimo, Dr. William H. Clark, aged 68 years.

EVANS.—Early on Thursday morning, April 28th, Anna Richards, daughter of the late Wm. H. Richards, wife of Horace Y. Evans, M. D., of this city.

HAMERSLY.—In this city, on the 26th ultimo, Edwin S. Hamersly, M.D., in the 65th year of his age.

McGEORGE.—On the 25th ultimo, Annie F. McGeorge, wife of Wallace McGeorge, M.D., of Woodbury, N. J., and youngest daughter of the late Hon. Isaac Pullen, of Hightstown, N. J.

PARMELEE.—At Watertown, N. Y., April 18th, 1881, S. L. Parmelee, M.D., in the 53d year of his age.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

ON TETANY.

BY DR. N. WEISS,

Of Vienna.

Translated for the Medical and Surgical Reporter.

The affection of which I am about to speak belongs to those disturbances of the nervous system which we are wont to call neuroses; in other words, to those affections which we believe to be caused by changes in the nervous system, which changes, however, cannot be demonstrated as yet.

We have in tetany an ailment whose clinical character can be demonstrated with entire precision, and for which we can frame a well-defined clinical history, but whose anatomical character has not been revealed as yet.

The affection is characterized by a series of paroxysms, which are divided by longer or shorter periods of freedom, during which there is little or no trouble complained of or discoverable in the muscles which were affected by the spasm.

The attacks are almost always preceded by perverse sensations; these consist of rigidity and darting pains in the hands, forearms, and legs, somewhat seldomer of the sensation of formication in these parts; this is soon followed by stiffness in the arms and legs, so that they are moved with difficulty, and immediately thereafter the spasm is fully developed.

The latter attacks the upper extremities most frequently, and causes such a degree of rigidity, especially of the forearms and hands, that even passive movements of these parts are rendered impossible.

The position in which the hand is found is variable, owing to the predomination of the spasmodic contraction in the flexors or extensors. Often the thumb is found violently adducted and the fingers pressed together and over it; the hand is made hollow by the approach of the ulnar to the radial side, and is best described by Trousseau, as the hand of the obstetrician when introduced into the vagina. This position of the hand is characterized by Trousseau as almost pathognomonic of this affection.

In other cases the thumb is pronated and bent and the fingers closed over it so tightly that the impression of the nails is often left in the palm. In exceptional cases the pressure is so severe and long continued that, as is reported by Herard, sloughs may be produced.

In still other cases the thumb is protruded between the middle and index fingers.

In all these cases there is generally a more or less severe ulnar flexion of the hand in the carpal joint. In some very rare cases the hands and fingers are found to be violently extended and the fingers standing far apart. With these positions of the hands the forearms are generally found half bent on the arms, the arms firmly adducted, and the forearms thereby crossed over the epigastrium. In rare cases, however, the arms are found to be abducted.

In many cases, and especially in the beginning of the affection, the spasms are confined to these regions. In a vast majority of the cases, however, and especially later in their course, the spasmodic contractions spread to other groups of muscles; in particular to the lower extremities; yes, there are even cases in which the spasms are entirely confined to these parts. The lower

limbs are almost always found adducted and extended, and the feet in a position of violent plantar flexion.

In severe cases there is also found rigidity of the muscles of the abdomen, trunk, and back.

The tonic contraction of the muscles of the chest and abdomen, by hindering the movements of the diaphragm, evidently give rise to difficult respiration, and even without participation of the diaphragm, to excessive dyspnœa and cyanosis. If the muscles of the neck are also affected, they prevent the flow of the venous blood from the brain, and in such cases there is produced excessive cyanosis of the face, and I have even seen one case in which it produced insensibility at the height of the paroxysm.

The spasms of the muscles of the back cause either opisthotonos or pleurosthotonos. As a rule, however, we find opisthotonos, just as in tetanus.

When the affection has reached such an intensity, the patient will present the same picture as would one suffering from tetanus; the more so because in such cases trismus and tonic rigidity of the muscles of the face are often present. But even in this stage tetany can be distinguished from tetanus if we regard the fact that in tetany the spasm never originates in the masseter muscles, which is the rule in tetanus, if we observe that the spread of the spasm is always from the periphery to the centre, while in tetanus the contrary is the case, and finally, that in the severest paroxysms of tetany there is never present that extreme degree of reflex sensibility which is found in tetanus. Then, if we have the opportunity to observe such patients for a longer period of time, we can convince ourselves that there exist periods during which they are entirely free from the complaint, which periods may last for hours, days, weeks, and even, as some observers teach, months, a condition of things which is not found in tetanus.

During the paroxysms the patients complain of severe pains in the affected muscles; these, however, disappear entirely with the cessation of the spasm.

The cessation of the spasm, which, like its beginning, takes place gradually, is often accompanied by the sensation of formication.

During the paroxysms there is sometimes a condition of anæsthesia in the extremities, so that patients are unable to distinguish the surface of any substance with which they are brought into contact, and if they put their feet on the floor they seem to be walking on a soft carpet.

Sometimes the temperature rises (to 104° F.) during the paroxysms, but I regard this as accidental, as I have only observed a rise in temperature once in twelve cases. Besides these symptoms there have been observed headache, vertigo, and tinnitus at the moment the attack begins.

In the intervals between the attacks, the patients, in many cases, with the exception of a slight stiffness and immobility, which lasts for a short time after the cessation of the spasms, feel perfectly well and go to work again at their occupation. In some cases, however, there have been observed tonic rigidity of one or the other of the muscles of the extremities.

The duration of the paroxysms and of the intervals between them differ greatly. In general it may be stated that the intensity of the spasm is proportional to its duration, as intense spasms generally last for hours; this, however, is not always the case. In the milder cases the paroxysms last from a few minutes to a quarter of an hour; in the more serious cases, however, they may last for hours; yes, there have even been cases observed, in which they have lasted for from one to three days. These latter, however, apparently consisted of a continuous recurrence of various spams.

The length of the intervals between the paroxysms varies still more. In most cases they vary from a few hours to as many days; there are, however, cases in which the intervals last for weeks, and even several months.

Of especial importance in diagnosing this affection is the so-called symptom of Trousseau, and the peculiar electric excitability of the affected muscles and their nerves.

The symptom of Trousseau consists of the possibility of producing a typical spasm in the affected muscles by pressure on the arteries or nerves leading to the parts. The compression must be continued for one or two minutes before the spasm is produced, and the latter lasts until the pressure is discontinued. The electric excitability of the peripheral nerves is increased to an extraordinary degree, as well by the faradic as by the galvanic current.

A very important diagnostic point is the increased excitability of the nerves by mechanical means; this is best observed by light percussion of the facial nerves. If we strike the face, in the region of the pes anserinus, with the tip of the finger, an instantaneous contraction of the muscles on that side of the face will be produced.

This phenomenon is so easily produced that I would recommend its trial in all cases which are in doubt, and only resort to Trousseau's method in case it prove unsuccessful.

This reflex contraction of the facial muscles can sometimes not be produced, but in cases where it can be demonstrated, I think it pathognomonic of this affection, as I have not been able to produce it in any of the other neuroses.

As regards the ætiology of this affection: It is an important fact that it almost always attacks young subjects. There is a remarkable predisposition to it in young children (from four to six years); the largest number of cases, however, occur between the sixteenth and the thirty-fifth year. Pregnancy, childbirth and lactation are predisposing causes. Formerly the occupation of the patients was believed to be a predisposing cause (shoemakers and tailors), but closer observation has failed to confirm this opinion.

As occasional causes, cold, especially working in wet, cold rooms, working in cold water, sleeping on moist ground, may be stated. An important cause is intestinal irritation, the presence of entozoæ, etc. Tetany is not infrequently a sequence of variola, Bright's disease, intermittents, cholera, and dentition.

In exceptional cases it has been observed to follow violent emotional excitement.

I have observed that tetany is most frequently met with in the months of January, February, and March, and I would not have the possibility of an active genus epidemicus positively excluded.

I would also call especial attention to the fact that I have repeatedly known tetany to supervene after extirpation of the thyroid gland.

The pathology of this affection is, as already stated, almost entirely unknown. It is not even proven beyond a doubt that the seat of the trouble is the medulla spinalis, even if we include the medulla oblongata. My own opinion, however, is, that the affection is caused by a condition of irritation of the anterior gray columns of the cord, and that this irritation is caused by variations in the blood supply to these parts. The ætiology of many cases speaks for the connection of tetany with the irritation of sympathetic nerve fibres in the periphery. There seems to be a constantly present and periodically increased interruption in the innervation of the vessels in the gray substance of the medullæ oblongata and spinalis.

Our knowledge of the pathological anatomy of this affection is also very meagre. Langhaus found the nervous elements of the cord unchanged, but the vessels of the white commissure and of the anterior horns showed remarkable changes. These changes he designated as pericarteritis, and periphlebitis, as they consisted mainly in an unequal thickening of the adventitia of these vessels, which was produced by a deposit of cellular elements, granules, and pigment. I have, however, been unable to verify any of these changes.

The diagnosis of tetany cannot be difficult if the symptoms which I have mentioned are carefully considered.

The prognosis is generally favorable; only in very rare cases does death result.

The therapeutics of tetany consists, for the milder cases, in a mere expectant treatment and the removal of any predisposing causes. If the paroxysms are severe and often repeated, subcutaneous injections of morphia should be given during the paroxysms, and hydrate of chloral 4.0–8.0 (ʒj–ʒij) p. d., in the intervals.

Bromide of potassium, in large doses, 5.0–10.0 pro die, may also be given.

The application of ice-bags to the cervical region during the paroxysms is attended with beneficial results. The treatment with electricity has not been attended with success.

Warm full baths, arm-baths, and cold-packing of the extremities are also said to act beneficially.

Communications.

THE UNDEFINED POISONOUS QUANTITY OF MORPHINE.

BY A. S. HUDSON, M.D.,
Of Stockton, Cal.

There is alacrity with which morphine saves life; there is tardiness in its action to destroy life. The curative dose is undefined; the quantity is whatever is needed for the case in hand. The amount required to destroy life is likewise undefined; so that in some constitutions the drug is *not* poisonous in any known quantity.

The wife of Dr. Case, of California, who died of that painful malady, cancer of the breast, uniformly got rest and immunity from pain with one-sixteenth of a grain of morphia, taken by the mouth. She was unable to bear a larger dose, and, as the case advanced to the final loss of life, it never became necessary to increase the size of it above that small amount. In that instance a grain or a grain and a half might have proved fatal to life. This case is an exception to the requirements usual for the use of the drug.

The number of instances in which it will not prove fatal to life is, perhaps, larger than is generally believed.

Most of the recoveries following a frightful

dose have got well after strenuous restorative efforts have been made, and the recovery is naturally ascribed to those efforts, and particularly to the agents therein employed.

Thus Dr. W. F. Norris, *American Journal of Medical Science*, October, 1862, attributes to belladonna the property of an antidote to opium; and to opium the antidote to belladonna. But as these agents are generally used precipitately, and also conjoined with others, the exact influence of the one or the curative agency of the other are alike hasty and mixed; and self-deception obtrudes as the misleading goal. In the *cures* reported by Dr. Norris, he seems to take no account of the systemic resilience to hurtful agents.

In the instance where he reports some seventy-five grains of morphine to have been swallowed, it was nearly three hours before full narcotism set in. The patient had been vomited with sulph. of zinc, and a strong decoction of coffee was given before belladonna was resorted to; and then recovery of the patient is ascribed to belladonna; when in reality, there is no evidence to believe that belladonna exerted any influence in the case, save to change the pupil from small to large size.

It is quite probable the man would have recovered if nothing had been done.

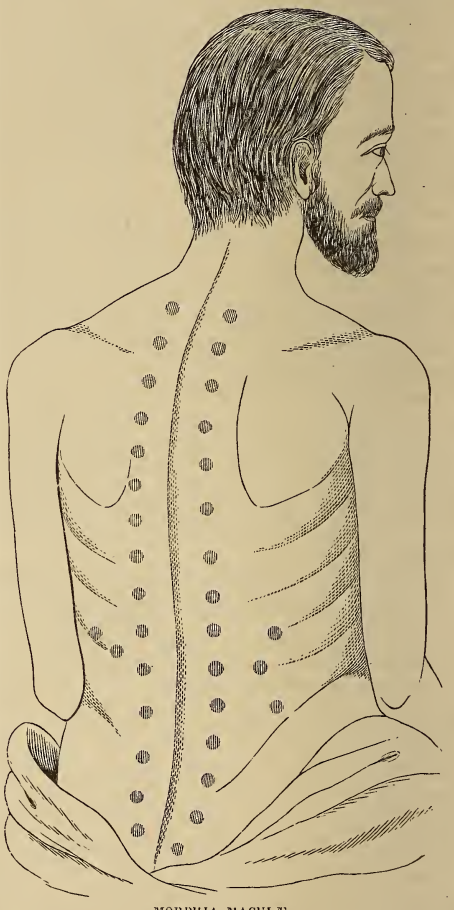
Dr. Norris mentions the number of respirations were eleven per minute. Two cases of profound narcotism that came under the observation of the writer, a man of thirty-five years, and a young woman, presented still more remarkable respiratory features. The man had resorted to opium for relief from a painful fistula and recklessly took an overdose. The woman was narcotized with hypodermic injections of morphia, therapeutically employed. The pupils of the eye in both presented the pin point contractions, and their breathings were, in each case, a little over one respiration per minute, or more nearly, three respirations in two minutes.

These patients recovered with merely watching and an occasional shaking, to start the breathing. If belladonna had been given, the "cure" following could have easily been ascribed to it. There is as much reason to believe belladonna or atropia will augment the hurtful powers of opium as to look for any other result.

The following noteworthy case, with the carefully prepared drawing, was kindly furnished me by A. T. Hudson, M D., physician to the San Joaquin County Hospital, California.

Frank Grinnell, from Texas, aged thirty-seven, married. Overborne by despondency he resolved to end his life, and took two bottles of morphia, each containing one drachm, about six P.M., November 15th, 1879. The drug failed to answer the hopeless intention. The next morning the man could not walk, suffered from pain in the limbs, back and stomach. He vomited all food and drink. Admitted to the hospital the 19th.

A singular eruption was observed upon his back, as shown in the figure herewith, of which there was no history. It presented two rows of



MORPHIA MACULÆ.

rose colored spots, nearly the size of a dime piece, symmetrically arranged on either side of the spinal column, and numbering fifteen on either side, and three spots over each kidney. They had no raised surface, nor did they disappear on pressure. After several days the spots gradually faded and disappeared.

Doubt was expressed about the quantity of morphine Grinnell had taken. All the evidence consisted in the two empty bottles found near his bed, with their labels, and the statement of

the patient himself. He got well and left the hospital. But some two weeks later Grinnell was found dead in bed, with two other empty morphine bottles and with a nearly empty half-pound bottle of chloroform near him.

It appeared that, to make sure of self destruction, he had supplemented the opiate with the inhalation of chloroform. This kind and amount of unhappy proof confirmed the truth of Grinnell's statement; and we were now obliged to believe that on the prior occasion he had, as he said, swallowed the two drachms of sulph. morphia at one dose; and that he would probably have survived the second two drachms, had he not added thereto the chloroform. In his case morphia by itself would not kill, but was fatal when united with the action of chloroform. This case presents the visible effects of the cerebro-spinal action of opium in a startling manner. At the post-mortem, the above mentioned spots had returned with their original form and brightness.

Therefore, there is no telling beforehand what will prove a fatal dose of morphine. Nor is there any telling, after a recovery from its threatening power, what was the curative agent.

Hospital Reports.

UNIVERSITY OF NEW YORK CITY.

CLINIC OF WILLIAM M. POLK, M.D.,

Professor of Obstetrics and the Diseases of Women and Children.

Laceration of the Perineum.

The first patient, gentlemen, whom I shall show you, presents a difficulty which is likely to arise at childbirth, usually at the first one. At first the patient may experience little inconvenience from the difficulty, viz., laceration of the perineum, but after a while, owing to changes which take place, she begins to suffer from various complaints, most of which are well illustrated by the patient before us. In order that we may have a thorough understanding of the case before we proceed with the operation, let us find out just what she complains of.

In answer to my questions, she says she is twenty-nine years old, that she has had five children, her first confinement being thirteen years ago, and the last one four years ago. She states that she feels no soreness, no pain, and that she is quite as well as any of us, only that her womb is down; she knows that her womb is down, because when she walks, or strains at stool or micturition, she feels that it comes down. She says she has no pain in the back, is regular in her menses, has no leucorrhœal discharge; her bowels are regular; once in a while, however, she does have trouble in passing water; she wants to go frequently, and passes but little at a time. And I may say that rest relieves this difficulty with the bladder, for under the quiet of the hospital during the past week she has not suffered any in that respect.

That, gentlemen, is about all the history we can get from this woman. Now, she is a robust looking woman, and it is unnecessary in this case to wait for time to build up her constitution, or put it in good condition for success to attend the operation for laceration of her perineum. I have spoken to you before of the importance of first treating the patient for an anæmic condition, a low condition of the system, if such happen to exist, before performing this operation; and I will not refer to it again, more than to remind you of the importance of doing so. In a large general hospital it is generally necessary to put the patient under a course of tonic treatment before you will be able to succeed in getting primary union from a plastic operation. Since this patient is in a robust state of health we have had to wait only for her menstrual period to pass over. Of course no operation should be performed about the vagina or uterus during the menstrual flow; not until it has fully ceased.

A first glance at her external genitals shows no abnormal condition, but when the labia are separated, and she makes a bearing down effort, you can see at once that all is not right; the perineum is lacerated down almost to the sphincter ani, and the anterior and posterior walls of the vagina prolapse. The tear is in the second degree. It has healed up a little in the angle near the rectum, by granulation. Now, when this woman makes bearing down efforts, as she does in defecation or micturition, there being no support to the vaginal walls, there is, in the first place, a rectocele; that is, a downward and forward projection of the posterior vaginal and anterior rectal wall, and, secondly, a cystocele, or a prolapsus of the anterior vaginal wall and base of the bladder. Now, when we introduce the finger into the rectum, we find between it and the vagina, not the thick triangular body which should represent the perineum, but a very thin structure, not more than a quarter of an inch thick at its deepest part, and higher up there is no perineal body; only a thin wall represented by the anterior rectal and posterior vaginal walls, which prolapses as she makes an effort at expulsion. Such is the condition of things at the external orifice; now, let us see what is the condition within the vagina. The cervix uteri is not more than an inch from the labia, which is entirely too near the vaginal orifice; the cervix is carried forward nearly up to the symphisis pubis, while the body of the uterus is thrown somewhat backward into the hollow of the sacrum. In other words, there is the first stage of retroversion. Grasping the body of the uterus between the two hands, one on the abdomen and the other in the vagina, we find that it is enlarged.

We have here, then, just the condition of things which favors procidentia of the uterus; it could not be better demonstrated upon any patient. Let us consider what are the supports of the uterus, for it is upon the integrity of these that the maintenance of the uterus in its proper position depends. It is generally supposed that the uterus depends upon the round ligaments, the broad ligaments, and the utero-vesical and

utero-sacral ligaments for the maintenance in its proper position in the pelvic cavity. Now, it can be shown, by pulling the uterus down with a strong tenaculum, as we have so often to do in operating for laceration of the cervix, that it is the sacral ligaments which under certain circumstances tend to hold it in position, and which are dragged upon when the uterus is pulled down; that the broad ligaments and the utero-vesical ligaments are relaxed, and can have very little to do with maintaining the organ in position. The ligaments, therefore, have little to do with the maintaining the organ in proper position until it has descended some distance into the vaginal canal, and then the only ligaments which come into play are the sacral. Then there must be some other tissues upon which the uterus depends for support, and they are those upon which the organ rests, and these, in turn, depend upon the perineum for support. Now, if the entire perineum and vagina, and all tissues below the uterus be removed, the uterus and its appendages would undoubtedly descend, fall into the space below. The perineum is the one structure, the abutment, so to speak, which stands between the rectum posteriorly and the vagina anteriorly, and upon the integrity of this body depends the support of those structures which more immediately retain the uterus in position. The rectum, you know, descends down the pelvis to the left of the median line, until it gets to a point a little above the sphincter ani, when it reaches the median line, then, descending along the anterior curve of the sacrum unto within about an inch of the anus, it makes a sharp turn backward. The point at which this turn is made represents the upper portion of the posterior surface of the perineal body. Now, in the well person the fecal matter, as it descends into the rectum, strikes against the anterior wall of the rectum, resting against the upper posterior surface of this perineal body, and is then deflected backward by this wedge-shaped mass, the perineal body. Now, if the wedge-shaped perineal body be destroyed, as it is in this woman, the fecal matter will find nothing to resist it and deflect it backward when it reaches the point referred to, and the rectum will be pushed forward into the vagina, forming a rectocele. If there were here a good perineal body it would prevent the prolapsus of the anterior rectal and posterior vaginal walls. Now, you will remember that the posterior wall of the vagina is attached to the uterus at about the junction of the body and the cervix; therefore, when you make traction upon the posterior vaginal wall, you, of necessity, make traction upon the posterior wall of the uterus itself, and the uterus is dragged lower down into the pelvis, the cervix being drawn forward and the body thrown backward into the hollow of the sacrum. Now, while traction is made upon the posterior wall of the uterus by the posterior wall of the vagina, a certain amount of traction is also made upon the anterior wall of the uterus by the anterior wall of the vagina, for the anterior wall of the vagina rests upon the posterior wall, the two being in so close juxtaposition that no air can enter unless they be separated. The bladder, resting upon the anterior wall of the vagina, descends along with the uterus when this support is taken away. You see, therefore, how important a part the perineal body plays, and when it is destroyed its restoration becomes a matter of primary impor ance.

Now, destruction of the perineal body is not always the only element at work in causing prolapsus of the uterus. There is usually a certain amount of sub involution, which, possibly, may be due to some laceration of the cervix, or the constitutional condition of the patient; that is, the uterus remains somewhat enlarged, and does not return to its original condition before pregnancy; the measurement of its canal may be represented by three inches, or three and a half. The uterus being enlarged, it, of course, tends, of its own weight, to fall, and the support from below then becomes more important; and when the two conditions exist—increased uterine weight and a weakening of the support below—you have a state of things most favorable for procidentia of the uterus. Now, in this patient, you would soon have not alone rectocele and cystocele, but a prolapsus of the uterus down to or below the vaginal orifice, one of the worst conditions we have to deal with in gynæcology.

Now, what we propose to do in this case is, first, to restore the perineal body, not simply sew it up externally, but restore the whole perineal body. The rest which the woman will have to take after the operation, for proper union to take place, will have a good influence upon the uterus also; but if afterward we find that organ still enlarged, we shall adopt measures for its support and its return to a normal condition. In performing this operation the lacerated tissues will be denuded from about the lower edge of the remains of the nymphæ to the angle next the anus, and you will find that this is a tedious procedure. Having done this, sutures will be passed in, drawing the denuded opposing surfaces together, the first suture being passed close to the angle next the anus, deeply into the tissues between the anal and vaginal walls, and drawn out on the opposite side; then about five more stitches, one after the other, will be passed higher up, and one just above the denuded surfaces, so as to bring all of these surfaces perfectly in apposition. After the insertion of the sutures, composed of silver wire, they will be twisted and the denuded surfaces thus brought in contact, so as to unite and form a new perineum. If this laceration had been greater, extending through the sphincter ani, we should have a more difficult job to accomplish, namely, restoration of the perineum and also of the sphincter muscle of the anus.

Malignant Uterine Disease.

This patient, gentlemen, does not speak the English language, and I shall have to give you her history as it could best be obtained from her. She is about forty-seven years old, and has had five or six children. Her health was good until a year or more ago, when she noticed a greater loss of blood than usual at her menses, but as she was at about that age when a change of life is expected, she supposed it was due to that fact, and paid little attention to it. Later she had some pain and a feeling of weight about the

genital organs, but being rather averse to consulting a physician, she let matters take their course until about six months ago, at which time her general health became so much reduced that she found it necessary to seek relief. We cannot gather any definite information regarding the examination which she received at that time, but when she presented herself at the hospital there was some emaciation, though not a great deal; there was a great deal of loss of strength; the bleeding was considerable, and grew more profuse, and caused considerable anæmia. There was also a yellowish-brownish appearance about the skin, which could not be accounted for by simple loss of blood. She had no symptoms referable to the rectum or bladder, and so far as she could judge, she had simply some uterine complaint. Now, you see, there is nothing very definite in such a history; several conditions which often exist at this time of life might give rise to the symptoms which she narrated. Her chief symptom is bleeding, and this often occurs, as before said, at this time of life. On making an examination you will find, in some instances, that it is due, simply, to a polypus, or a fibroid tumor, and if so, it may be considered fortunate, for these can often be relieved without much difficulty. Again, it may be due, simply, to a granular degeneration of the lining membrane. There is another condition which, although not particularly liable to occur at this time of life, may do so and give rise to hemorrhage; and women are apt to think it more liable to make its appearance then than at other times. I refer, of course, to carcinoma. The points, then, which we have for consideration are, whether this bleeding be due to granular degeneration of the mucous membrane of the uterus, a condition which occurs frequently at this period of life; or, whether it be due to a kind of hyperæmia which is liable to occur at this time, not connected with any special change in the mucous membrane of the uterus; or, whether it be due to a fibroid tumor or a polypus; or, lastly, whether it be due to carcinomatous degeneration.

Now, if it be cancer of the uterus, you would expect to find its seat in the cervix, as it occurs there more frequently than in any other portion of the uterus. Will one of you please come forward and make the examination? Now, Doctor, if there be cancer of the cervix, in what condition would you expect to find it? "Enlarged, indurated, nodular, and it would probably bleed readily." Yes, sir; especially if the cancer had existed for some time, it would probably bleed quite readily, and it is for this reason the examination should be made with the greatest care. A portion of tissue may be scraped off with the finger, a little bleeding may occur at the time, but not sufficient to specially attract the attention of the examiner; the patient may go home, and after a few hours the doctor may be sent for in haste, and going to her house find her greatly reduced from loss of blood. This accident is especially liable to occur when the speculum is used, and for this reason the examination should not be made with the speculum, except it be absolutely necessary to do so. These are practical points, and I will mention another. Patients having such symptoms as this woman has complained of, rarely think they have cancer; and you may, upon making an examination, find a cauliflower-like growth, which, being touched, bleeds readily and freely, and it is to this fact, the result of your examination, that the ignorant class of patients are apt to attribute the commencement of malignant disease. An example of this kind occurred in this hospital lately. About a year ago a woman was admitted who had a cauliflower like growth on the cervix, pointing plainly to cancerous degeneration, but, wishing to conceal the fact from her, to prevent mental depression, she was not told of it, and I tried not to use a term in her presence which would render her cognizant of the fact that she had cancer. No hemorrhage occurred until later, when on one occasion, using Sims' speculum to make an application, a little bleeding occurred. She afterward went out of the hospital and remained some time, and then returned a victim of severe hemorrhages, perhaps the result of some treatment which she received outside. The hemorrhages were so severe that it was necessary, on a number of occasions, to tampon the vagina. The cancerous degeneration had involved the peritoneum and organs neighboring the uterus. The time had come to let it be known what was her true condition, and when she heard of it she said immediately, and believes now, that the cancer was caused by our examination at the time when hemorrhage occurred. It may not be best to tell the patient herself, at an early stage of the disease, that she has cancer, but her friends may be informed of the fact, or, at least, that she has an incurable disease, and thus avoid any such false impression.

Now, if the cause of this hemorrhage be a granular or fungous degeneration of the mucous membrane of the body of the uterus, will the cervix or os present any indications thereof? "Not necessarily." No, not necessarily; but if the granular degenerations be large and polypoid in structure, the external os may be more open than normal, and present some indications pointing to the affection; if the degenerations be small, it will offer very little diagnostic information. If there be a polypus, or a fibroid tumor, it may present in the cervix, and if it be of considerable size the body of the uterus will be so enlarged as to be recognizable by bimanual manipulation, and by the passage of the sound. If, then, cancer of the cervix be not clearly evidenced in itself, it may be diagnosticated negatively, by excluding other conditions which might give rise to the symptoms which exist; but cancer frequently presents conclusive evidence of its presence in itself, and, if required, a microscopical examination can be made. Now, besides the other signs of cancer mentioned, which are present in this case, there is a very offensive odor upon making examination, which is almost characteristic of this disease. I say almost, because even a portion of a polypus, in sloughing, may undergo degeneration and give rise to an odor of decomposing flesh, probably, however, not quite so bad as exists here. The disease has invaded other tissues in this case, so that the uterus is bound down, and the prognosis is altogether unfavorable. I speak openly before her, because she does not understand our language.

Now, the question arises, what can be done in such cases; for they cannot be abandoned altogether. As they live a varying length of time, from one year to two or three, the first indication is to improve or maintain the general health, as far as can be done by food and tonics, and general hygienic conditions. Then cleanliness, and getting rid of the offensive odor and leucorrhœal discharge, as far as possible, is indicated. Then, if there be much pain, relieve it by anodynes, and these are cases in which we are justified in using opium freely, if necessary, to relieve suffering. The patient cannot live a great length of time, especially where the disease has gone as far as it has here, and there can be no harm in making her comfortable during the remaining short period of her life, by the administration of opium. If the disease were in its earlier stages, and involved simply the neck, it might be amputated; but when other tissues have become infiltrated, as in this case, such an operation would be altogether unjustifiable. In cases in which there is great bleeding from the degenerated tissue, the loose part of this may be scraped off with the curette, and then cauterized with the actual cautery, the only safe cautery to use as a hæmostatic in these cases; nitrate of silver, sulphuric acid, and the caustic alkalies, are too difficult to limit in their effects. Thus, you see, very little can be done in these cases but to control symptoms and make the patient as comfortable as possible.

Medical Societies.

PENNSYLVANIA MEDICAL SOCIETY—THIRTY-SECOND ANNUAL MEETING.

First Day.

AFTERNOON SESSION.

(*Concluded from page* 586.)

At 2 P.M. the President called the Society to order.

Dr. Albert H. Smith, of Philadelphia, offered the following:—

Whereas, This Society has reason to believe that in a recent bill before the State Legislature, in reference to the organization of the Warren Hospital for the Insane, the principle set forth by this Society at the meeting at Chester, in 1879, and afterward embodied in a law enacted by the Legislature, recognizing the propriety of the female insane of the State being treated by physicians of their own sex, and their right so to be treated, has been ignored, and a plan of organization adopted or is about to be adopted, which will prevent the female patients of the Warren Hospital from being under the unrestricted control of female physicians in their medical treatment and general care;

Whereas, The correctness of the principles enunciated by this Society in this matter has been proven and clearly established by the thorough success of their practical working in those hospitals already organized in obedience thereto: therefore,

Resolved, That this Society does respectfully but earnestly protest against any action in relation to the State Hospital at Warren, or any other to be hereafter founded, which involves a retrograding from the principles recognized, by placing the insane female patients under the sole care of a male medical superintendent, or making the female medical officers subordinate to, or dependent upon, or controllable by such superintendent, or by any plan of organization other than one placing a woman practitioner in unrestricted and absolute authority over the medicinal, moral, and physical treatment of the female patients in State hospitals for the insane.

On motion, it was made the special order, as the first business for Thursday morning.

The amendments to the constitution, offered last year, were called up and discussed, but the hour having arrived for the address in surgery, further action was postponed.

The address in surgery was then read by Dr. S. M. Ross, of Altoona. He warmly advocated conservative instead of heroic treatment, unless the latter was absolutely necessary to save life or prolong life. Conservative and successful surgery are almost synonymous. The doctor described at some length several cases he had treated, in which the limbs, or parts of limbs, had been saved by conservative treatment. The profession are apt to be too unwilling to trust to nature's recuperations. Tight bandage of wounds, he said, has done more harm than all other causes combined, by obstructing the circulation. The antiseptic treatment of wounds and lacerations was commended. After the second battle of Bull Run, wounded men were permitted to lie on the field for many days before they could be placed in hospitals; all of them got well; while those who were at once placed in crowded hospitals died off, like rotten sheep, owing to the crowded condition of the hospitals, the impurity of the air and the medicine, etc.

Dr. W. B. Ulrich, of Chester, endorsed Dr. Ross's views, and gave the particulars of one or two of his own cases.

After which the paper was referred to the Committee of Publication.

Dr. Jacob Price, of West Chester, read a paper on "The Importance of Local Treatment in Congestion and Inflammation of the Cervix of the Impregnated Uterus." He took the ground that in very many instances, the double duty resting upon the physician is to alleviate suffering as well as to save life. The observations of the writer led him to the conclusion that in many cases the existence of inflammation of the os and cervix during pregnancy, and even when recognized, its bearing upon the comfort and, indeed, the safety of the patient, was not properly estimated. Its frequency, especially in the primiparæ, he believed, was much greater than is generally supposed. The over-mental strain and physical exertion involved in the establishment of a new home, the prolonged standing at reception, as well as the disturbance of frequent sexual intercourse, conspire to its development in this class of patients, and their timidity and reticence are likely to keep the true difficulty hidden, unless the medical attendant is carefully on the alert to detect it. The presence of the fœtus he believed an aggravating influence, often bringing to light a cervicitis too slight for previous notice.

The local suffering, as well as the reflex disturbance, he believed much intensified by the presence of pregnancy. The latter in some cases is so profuse as to lead to a fatal result. He traced the history of five fatal cases, not heretofore reported, no two of these occurring in the practice of the same physician. A part of the paper dwelt forcibly upon the physical and mental suffering entailed by an obstinate case of the sick stomach of pregnancy, and urged in strong terms the duty resting upon the practitioner of giving them the most active care and sympathy.

Dr. Price claimed that most of these obstinate cases, defying, as they usually do, medicines directed to the stomach itself, were but a reflex disturbance, dependent upon a congested or inflamed condition of the cervix, and are to be relieved by treatment usually relied upon in cervicitis, viz: a soluble state of the bowels, rest in bed, and local treatment. His practice is to use the speculum, and apply to the canal of the cervix (a short distance) and its whole vaginal surface, a solution of iodine, crystallized carbolic acid, and tannin, each two drachms, dissolved, by the aid of heat, in an ounce of concentrated glycerine. Then to place in contact with the uterus a tampon of absorbent cotton, saturated with pure glycerine. This is kept in situ by a second large tampon of dry cotton. The osmotic property of the glycerine causes a free, watery flow for about a day, which unloads the congested vessels of the cervix, and adds to the astringent effect of the agents used. His success with this plan of treatment was most satisfactory.

From numerous cases, he selected two, that all through previous pregnancies had suffered from sick stomach and nervous depression, till life was a burden and the danger became imminent. These had failed to be relieved by the most careful and skillful general treatment, directed by physicians of acknowledged ability and experience. Both were promptly and permanently relieved by the course above indicated.

The use of the speculum, he urged, is not always essential. Medicated tampons placed against the cervix by means of the suppository tube, are sufficient in some cases, and in others vaginal injection of a simple astringent and anodyne solution. These he does not, however, regard as effectual, or as safe as the direct application by means of the speculum.

The author had found the literature of this subject—in view of its bearing upon the welfare of so many sufferers—strangely merged. Dr. T. H. Bennett was the only one that had clearly and fully traced the dependence of the obstinate vomiting of the patient upon an inflamed cervix. Cazeneauve had given the subject considerable space, but had developed nothing in regard to its pathology.

The paper closes with an earnest appeal to physicians to give these cases the careful attention their bearing upon the safety and comfort of the patient demands.

Dr. Sutton, of Pittsburg, not only disputed the soundness of Dr. Price's treatment, but declared it to be based upon a false pathology, exploded hundreds of years ago, and revived again recently. Dr. Price found able advocates in A. M. Pollock, of Pittsburg, Dr. W. W. Dale, of Carlisle, Dr. Albert H. Smith, of Philadelphia, Dr. John L. Atlee, of Lancaster, and Dr. Ulrich, of Chester, all of whom, in general, accorded with Dr. Price in theory and treatment. The paper was then referred to the Committee of Publication.

Dr. S. D. Risley, of Philadelphia, read a paper on "Affections of Lachrymal Passages, their Nature and Treatment." Attention was given only to the affections of the drainage system of the lachrymal apparatus. Disease and consequent constriction might occur in any part of drainage tubes, resulting in retention of tears in the *cul de sac* of the conjunctiva. The presence of the retained tears resulted in lachrymal conjunctivitis, with thickening of the conjunctiva and blepharitis ciliaris, causing a red and watery eye. One of the most serious annoyances arose from the irregular refraction by the cornea, produced by the follicle of tears, which heaped themselves against the surface of the cornea on the border of the lower lid. Obstruction might occur at any point between the puncta and the nose. The style as a means of treatment for obstruction of the nasal duct was obsolete. The method of treatment now quite universally employed was that of Bowman, by slitting the lower canaliculus and probing the lachrymal duct. When the constriction was in the canaliculi this was unnecessary, since simple dilatation, without slitting the canal, was sufficient. Many cases of retained tears were due to a closure at the puncture only, and a few dilatations were sufficient to remove the trouble. When the stricture was in the nasal duct it was necessary to lay open the canaliculus well up to the sac, in order to secure readier access to the duct. The theory for the treatment by probing, in Dr. Risley's opinion, was pressure, and not the stretching or tearing of the stricture. Hence, a probe should be used sufficiently large to pass tightly, but not to rupture the tissues composing the stricture. It should remain until firmly grasped by the constriction, twenty to thirty minutes usually being sufficient. The constricted part was thus subjected to considerable pressure between the probe and the bony walls of the duct.

The old method of forcible dilatation by large probes was again being employed by some, but strenuous objection was made to this. Several skulls were shown, in which even the bony duct would not admit the larger probes of a series now recommended for use.

Acute purulent inflammations of the sac did not require to be opened on the cheek, since they could be emptied through the slit canaliculus, thus avoiding the conspicuous fistula on the face.

Dr. J. W. C. O'Neal, of Gettysburg, read a paper entitled "Contributions to the History and Use of Katalysine Spring water at Gettysburg." After referring to the battle of Gettysburg and its decisive results, Dr. O'Neal stated that many of the people of their section were left in an impoverished condition, and were compelled to look around and find means of support. Just west of the ridge on which Gen. Reynolds was killed is a mineral spring, which, up to that time, was held in small account; but the owner conceived the idea that it might prove valuable in

both a pecuniary and medical sense. The historic associations of the locality, the beauty of its surroundings, its variegated scenery and salubrious air, would of themselves be attractive to tourists, and if the waters of the springs should prove to be valuable, there was a fortune in them. The waters were analyzed and found to contain many valuable properties; they obtained notoriety through wide and judicious advertising, and are much sought by invalids, who are always hopeful. The speaker gave an analysis of the waters, and claimed that, properly used, they were beneficial in cases of gout, rheumatism, dyspepsia, diabetes, indigestion, and some other diseases. He thought, however, to secure lasting benefit, the patient should live at the springs, drink the waters and bathe in them, and inhale the pure air of the surrounding country, which is 550 feet above the tide. The paper was referred, as usual.

Dr. C. C. Seabrook, of Harrisburg, read a paper on "The Pathology of Shock." The speaker detailed the results of many experiments and vivisections made by him on this subject, and exhibited diagrams showing the rise and fall of the blood currents, as shown under the microscope in some experiments with wounded frogs, dogs, and rabbits. This was also referred.

On motion of Dr. C. A. Rahter, of Harrisburg, the amendment to the constitution, offered by him last year, was taken up:—

Article IV, Section 1. After the word Treasurer, add, "Judicial Council."

Also, By-Laws, Article I, substitute for Section 10:— "A Council, consisting of nine members, shall be elected, whose duty it shall be to take cognizance of and decide all questions of an ethical or judicial character that may arise in connection with the Society. Of the nine members of the Council first elected, the three first named on the list shall hold office for one year, and the second three named shall hold office for two years. With these exceptions the term of office of members of the Council shall be three years, three being elected annually.

"The said Council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said Council, on all matters referred to it by the Society, shall be final, and shall be reported to the Society at the earliest practical moment. All questions of a personal character, including complaints and protests, and all questions on credentials, shall be referred at once, after the report of the Committee of Arrangements, or other presentation, to the Judicial Council, and without discussion."

A motion by Dr. Jackson, to strike out "all questions on credentials," was, after some discussion, negatived.

The amendments, as originally offered, were then adopted by an almost unanimous vote.

On motion of Dr. T. Green, of Easton, the other amendments were made the special order for Thursday, after action on the first special business.

Adjourned, until evening.

EVENING SESSION.

Vice-President Dr. W. Varian, of Numidia, called the Society to order, at 7½ P.M. The President, Dr. J. T. Carpenter, of Pottsville, read the annual address.

The Doctor referred to the great progress made by the State Society since its organization in this city thirty-three years ago. Then it was weak and without organization; now it is strong and is a power in the land, and influences for the good of the people the legislation of the State. After recounting at some length the importance of the Society, its objects and duties, Dr. Carpenter entered upon the subject of his address, "The Treatment of the Insane." He stated that there are 45,000 insane persons in the United States, and that the ratio is largely increasing; that they belong to all classes of society, and that their proper treatment has become a question of overshadowing importance. Dr. Carpenter described, at considerable length, the treatment of the insane, both in this country and Europe, and while he gave our superintendents and physicians in charge of these institutions credit for doing the best they could under the circumstances, he declared our present system essentially wrong and far behind that of England and some other European nations. He argued that the superintendent of an insane asylum should be entirely exempt from business matters, such as the furnishing of supplies, keeping accounts, etc., and should devote his whole time to a scientific study of his patients and the training of his assistants. He complained that under the Pennsylvania system—or rather want of system—young and inexperienced physicians are selected to take charge of such institutions, instead of older and more experienced physicians, and that the number of physicians is far too small to properly attend to the patients. What is to be done with the convalescent insane is an important question, and one that appeals for early action. The English plan is far in advance of ours in this respect. There special wards are provided for the convalescent, apart from the asylum. These are often at the seaside or other pleasant place, where there is little or no restraint upon the patient. The transition from the asylum to the home should not be too sudden, as relapses are often thereby caused. Dr. Carpenter concluded by expressing the hope that the time was not far distant when the United States, now so far behind Great Britain in the treatment of the insane, will take a leading position and instruct Europe instead of receiving instructions from her.

On motion of Dr. John L. Atlee, the thanks of the Convention were tendered Dr. Carpenter for his address, and a copy was requested for publication.

Adjourned until 9 A.M. on Thursday.

Second Day.

The session was opened with prayer by Rev. C. F. Knight, D.D., after which the following announcement was made of members of the Nominating Committee:—

Allegheny, T. J. Gallaher; Berks, L. De B. Kuhn; Blair, George W. Smith; Butler, Samuel Graham; Chester, Jacob Price; Clarion, J. William Leadenham; Columbia, F. W. Redecker; Crawford, W. Varian; Cumberland, W. W. Dale; Dauphin, H. L. Orth; Delaware, J.

W. Phillips; Erie, J. L. Stewart; Fayette, R. W. Clark; Franklin, D. M. Unger; Huntingdon, J. W. Dinwiddie; Indiana, J. L. Crawford; Jefferson, M. M. Rankin; Lancaster, J. A. Ehler; Lycoming, Thomas Lyon; McKean, J. C. Elliott; Mifflin, H. Van Valzah; Montgomery, William Anderson; Montour, J. D. Mausteller; Northampton, A. Seip; Perry, M. B. Strickler; Philadelphia, L. Turnbull; Schuylkill, J. H. B. Amick; Venango, A. L. Potter; Washington, A. J. Patterson; Westmoreland, R. McConaughey; York, S. J. Rouse.

The preamble and resolutions offered yesterday by Dr. Smith, relative to female superintendents and physicians for the female patients in the insane asylum at Warren, and asylums elsewhere, were taken up. They were discussed at some length by Dr. Smith, Dr. Atlee, Dr. Traill Green, Dr. Corson, Dr. Curwen and Dr. Rahter, after which they were voted down, by a decided majority.

Drs. John Morris and J. A. Stewart, of Baltimore, representatives from the Medical and Chirurgical Faculty of Maryland, were invited to seats on the platform.

Reports of County Societies having been called for, on motion, those not ready were allowed two weeks in which to report directly to the Committee of Publication.

The amendment to the Constitution offered by Dr. J. T. Carpenter—

Article III. Section 2. The delegates shall receive their appointments from the County Societies, and from the College of Physicians of Philadelphia,

Was then discussed, and unanimously rejected.

The amendment offered by Dr. Dale was announced as withdrawn, the appointment of a Judicial Council having rendered it useless.

Dr. S. S. Schultz, of Danville, read the "Address in Mental Disorders":—

The following characteristics of insanity make it such a serious disease that it was for a long time supposed to be the result of a direct judicial infliction, by the Supreme Judge, of righteous punishment for aggravated crimes:—

It suspends or destroys the mental operations, by which alone man is raised above the brute.

It alters his moral character, so that he becomes suspicious, untruthful, cruel, impure, dishonest, and the object of judicial punishment.

It often exists in an undeveloped form for months and years, ruining the patient's reputation and finances, before the existence of a disease is suspected.

It is a slow disease, taxing the resources of the family, neighborhood and community for a long time, and, therefore, exhausting them much more often than in other diseases.

The mental torture of the patient himself, which drives him to self-destruction, or the murder of his dearest kindred.

It often, by reason of its hereditary character, makes several members of a family incompetent for their duties, and a burden to the public.

It requires, for its successful treatment, the removal of the patient from familiar scenes into new and hitherto strange surroundings. His case must be confided to strangers.

As soon as its true nature as a bodily disease no more mysterious than a catarrh, was understood, sympathy and pity prompted half-civilized States, even, to make provision for the cure and care of the unfortunate victim of so dreadful a scourge. In enlightened States, high judicial authority has pronounced the indigent insane the ward of the State, for which it is bound to provide by considerations both of policy and humanity.

Largely through the presentation of facts and arguments by the State Medical Society to the Legislature, five State hospitals have been established in this State, having room for 3000 patients. Because only about two-thirds of this room is occupied, it has been hastily inferred, and unwisely promulgated by the public press, that too many hospitals had been built and public money squandered for private ends. No greater error than this could be committed. There are at least six thousand insane people in this State, of whom a very small proportion can obtain such care and treatment, outside of State hospitals, as will give them even a decent chance for recovery, not to speak of such comforts and protection as are due to a fellow human being. That poorhouse accommodation is, at its best state, inadequate and unsuitable, is the universal opinion of those who are competent to judge.

That the insane should not be in poorhouses, or adjoining asylums, is strongly maintained by the State Board of Charities.

It was supported by a two third's vote at the State Convention of Poor Directors in 1880.

The legislation of every State of the Union is based on this idea, that the insane must be brought into State hospitals, controlled, supervised and managed by the State.

The question now arises, why are not the insane poor in the hospitals? If there are more insane than can be accommodated in the existing State hospitals, if they can only in these get the treatment which all acknowledge they should have, why, then, are there one thousand empty beds? The truth simply is, that it is a misnomer to call these State hospitals charitable institutions. Would that man be called charitable who fed the hungry and clothed the naked on the condition that he be reimbursed to the extent of four-fifths of his outlay, but turned others equally in need of food and clothing away from his door, hungry and naked, because they had nothing to pay in return? If a person guilty of such conduct should claim to be charitable, he would be denounced as an imposter and hypocrite, and justly so. Now what right have the State and these hospitals to appropriate the name charitable when they do the very same thing? When a poor district can't pay three dollars per week and clothing for the patient, he is not received, no matter how much he may need hospital care. Instead of resting with complacency when the past is contemplated, and assuming that the work is done, there must be legislation that will secure admission to the State Hospital to the poorest and most friendless in the poorest poor district of the State. When this is done, and not before, the State has done its duty toward the indigent insane.

One way of doing this is illustrated in Ohio, where nothing is charged to poor districts for the

support of the patient in the State Hospitals, for the State pays everything. Another illustration we have in Connecticut, where one half is paid by the State, and the other half by the poor districts. Were either of these plans adopted in this State, the State Hospitals would not be long vacant, and the public would then have discharged its duty toward the most helpless and pitiable citizens.

The paper was referred.

Dr. Curwen read a paper on "Rest in Nervous Diseases," in which he took the ground that, as a rule, nervous diseases were of an asthenic type, and that great and steady attention should be given to the proper nutrition after the removal of all disorders which might interfere with the proper performance of that function, and where any special disease prevented the proper nutrition, every effort must be made, by medical and hygienic measures, to sustain the system. That, as so many of the diseases of the nervous system were produced by over exertion and constant strain, men should endeavor to obtain half a day, or a full working day, in each fortnight, at the furthest, in which to enjoy a thorough rest, in place of waiting until the system was nearly run down, and then take it in that season when little rest could be had, by reason of the disposition on the part of the majority to fall in with the fashion, and travel, or lounge about watering places.

That, when disease actually influenced the system, every effort must be made to remove that, by the most careful attention and examination of every organ. That every man should have some object of interest to engage his mind and attention, outside of his regular duties, on the principle that change of occupation is rest. That students and men of literary tastes and habits should be careful to take regular systematic exercise, in order not to divert the blood too much from the spinal cord, which derived its supply, in great part, from the arteries which supply the brain, and if too great a demand was made by the brain for the supply, the lower spinal cord would suffer; but while using that exercise, it must be of a character not to tax too strongly the nervous supply to the lower extremities; that in actual nervous disease absolute rest is demanded in the earlier stages, and graduated rest in the later stages; that it is much better to insist on a large amount of rest, and not to urge the patient to take exercise to regain strength, unless special directions are given as to the kind and degree of exercise, which should be of such a character as not to draw too heavily on the nervous power, and thus increase the exhaustion; and that what is specially needed in the treatment of all nervous diseases is rest, to as great an amount as can be obtained. Careful graduated exercise, short of the point of fatigue, careful medication to strengthen the nervous and general system, and nutritious food adapted to the condition of the patient, and steady adherence to a plan which has been found, on trial, well adapted to the case, and the careful avoidance of all stimulants.

Dr. J. Tyson, of Philadelphia, spoke at some length of the value of electricity as an agent with which to exercise the muscles of patients. The paper was referred.

Dr. Traill Green, of Easton, read a paper on "The State Medical Society and the Preparatory Education of Medical Students." Dr. Green took the ground that many students enter the medical schools entirely unprepared; that many of them have scarcely the rudiments of an English education. This Society insists on higher qualifications, but there are large numbers of physicians who do not belong to the State or County societies, and these cannot be reached and cannot be made to conform with the rules of the Society; but they and their students can be reached by the medical schools demanding a higher requirement on the part of pupils, and refusing graduation to those who do not attain the proper standard. It is a disgrace that many young men, fresh from the college, are rejected as unworthy or unfit, when they apply for positions in the army and navy. After remarks by several the paper was referred.

Dr. John L. Atlee, of Lancaster, asked for information whether the Philadelphia County Medical Society had ever complied with the rule of the State Society requiring county societies to appoint an examining committee to report upon the standard of preparation of applicants.

The secretary answered that such committee had been appointed.

Dr. Oscar H. Allis, of Philadelphia, read a brief paper, entitled, "In what should preliminary examinations consist, and what steps should be taken to make them uniform throughout the State?" The paper was discussed at some length by Drs. Sibbet, Pollock, Findley, and others, and a resolution adopted for the appointment of a committee to report at next annual meeting a schedule or form to be used by county medical societies and members of the same, requiring preliminary examinations of applicants prior to accepting them as students of medicine. The chair appointed the following gentlemen said committee: Drs. O. H. Allis, Traill Green, W. R. Findley, J. B. Roberts, and W. B. Ulrich.

Dr. Wm. B. Atkinson presented a report from the Committee on State Board of Health. The action taken by the legislature during its present session was recited, showing that the Senate bill relative to said board had failed to become a law, through the unavoidable absence of some of its friends in the House, but that the matter has been reconsidered, and the House will probably pass it before adjournment.

By request, Mr. John Norris read the names of those members of the House who had voted against the bill or failed to vote, and urged members of the Society to use their influence with those members in behalf of the bill.

A resolution was presented and unanimously passed, in approval of the Senate bill, and urging its speedy passage.

Dr. O. H. Allis, of the Committee on Rules of Order, reported a series, altering in some respects those now in force. They were adopted and ordered to be printed.

Dr. John Curwen asked the discharge of his Committee on Epilepsy and Insanity, as none of the county societies had reported to him on the subject.

This was agreed to.

Adjourned until 2 P.M.

AFTERNOON SESSION.

The president called the Society to order at 2 P.M.

The address on Hygiene was delayed by the absence of Dr. Lee.

Dr. Wm. Goodell, of Philadelphia, read a paper on the "Extirpation of the Ovaries for Insanity." He detailed a number of cases in which an artificial menopause was thus produced, and with favorable results.

The paper was discussed by Drs. Curwen, Atlee, and Kerlin, and referred as usual.

The address in hygiene was read by Dr. Benj. Lee, of Philadelphia. The subject chosen was "Certain Matters in regard to the Purity of the Air, especially in large cities." It was considered under the two general heads of the air of the street and the air of the home, while the latter was viewed in respect, first, to preserving, and secondly, to restoring its purity. The first point discussed was the composition of street dust. While it contained in addition to earthy matter, which was comparatively innocuous, spores, disease germs, epithelial scales, vegetable cells, etc., as lately pointed out by Dr. Leidy, in it were also found all the products of decomposition of animal and vegetable refuse, together with small particles of iron minutely subdivided. Was it not possible that all these elements being taken into the air-cells, might there undergo fermentation, poisoning the blood at its source, and thus producing the rapidly fatal cases of so-called typhoid pneumonia with which we are so unfortunately familiar, and of which the recent sudden death of a distinguished divine visiting Philadelphia was so lamentable an instance? Under such circumstances the development of cyanogen might reasonably be anticipated, and all the elements for the formation of the cyanides, even of ferrocyanide of potassium, were present. Such a process of decomposition, fermentation, and reconstruction had, in the speaker's experience, been fatal to a large number of trees in the New York Central Park, from the use of street manure. The most dangerous part, as well as the larger part, of the street dust is horse droppings. This should never be allowed to become a part of it. Under a rational system of scavengering it should be taken up while moist, immediately after deposit, instead of being allowed to be ground up into fine dust, and distributed through our own bodies and houses.

In regard to the purity of the air of our houses, the dangers of sewer gas were alluded to, and the defects of the ordinary water trap pointed out. As a more efficient and additional means of protection, a new contrivance, called the Sewer Gas Mercury Seal, was exhibited, in two different forms, the one intended for the water closet, the other for the kitchen sink and toilet basin. Finally, in order to destroy impurities in the air of a house or room, whether from the last mentioned source or from exhalations from the bodies of the sick, ozone was referred to as possessing all the qualities of other gaseous disinfectants, in an astonishing degree. A simple but ingenious contrivance was shown, called the American Ozone Generator, by means of which a constant development of this form of oxygen could be kept up in the sick room, in quantities claimed to be sufficient to neutralize the noxious emanations from a case of scarlet fever.

Dr. Leffman, in discussion, said: I venture to take exception to some of the points advanced in the address, and, first, in regard to the mercurial sewer trap. Complicated machinery is always objectionable in such apparatus. It is liable to get out of order, and such disarrangement is likely to be unnoticed or uncared for, and the attachment will then become worse than useless. I regard it as indispensable that a sewer-trap should be a perfectly simple contrivance. I see, also, additional objection in the fact that mercury is used in considerable amount. Many cases of poisoning by vapor of mercury are on record, and the effects of this vapor are all the more dangerous because of their insidious nature. Mercury also easily dissolves a number of metals, and the amalgams thus formed will act upon metals which pure mercury will not attack. I think, therefore, that in actual experience, this sewer-trap will be found dangerous and inefficient.

I feel that the same kind of criticism must be given to the "Ozonizer" which has been exhibited. Phosphorus is exceedingly dangerous. Inexperienced persons cannot handle it without almost certain injury, and, like mercury, it easily becomes the source of chronic poisoning. To keep such an apparatus as the one here presented in a sick-room would be highly objectionable. The amount of ozone which it could produce would probably be of little service. With the gaseous disinfectants that have corrosive qualities, the difficulty is that they do not produce much effect unless used in such proportion as to corrode and destroy the majority of the articles in the room. Instruments will be rusted, curtains, clothing, and pictures damaged, and even then the disease germs may escape. Ventilation, cleanliness, and for portable articles, the employment of a high temperature, 250° F., or thereabouts, are the proper methods of disinfection.

In regard to the production of Prussian blue, I doubt the possibility, or, at least, the probability, of its formation in the manner described. Even should it be so formed, we must remember that it is quite insoluble, and is one of the least active of the cyanogen compounds.

The paper was also referred.

The Committee on Nominations reported, through their chairman, Dr. J. Aug. Ehler, as follows:—

The Committee on Nominations would respectfully report the result of their deliberations, and name the following persons for officers of the Society for the current year:—

President—Jacob L. Ziegler, Lancaster Co.

Vice Presidents—1st, Joseph A. Reed, Allegheny County. 2d, W. S. Roland, York County. 3d, J. W. Houston, Chester County. 4th, W. Murray Weidman, Berks County.

Permanent Secretary—William B. Atkinson, Philadelphia.

Recording Secretary—G. Thickston, Erie Co.

Corresponding Secretary—O. H. Allis, Philadelphia.

Treasurer—Benjamin Lee, Philadelphia.

Place of Meeting.—Titusville, Crawford co. *Time.*—Second Wednesday of May. 1882.

Resolved, That Wm. Varian, of Crawford co., be chairman of the Committee of Arrangements, and that the Crawford County Medical Society is hereby instructed to name his colleagues on said Committee.

The Committee of Publication—Drs. Wm. B. Atkinson, Benj. Lee, Wm. Goodell, O. H. Allis, J. G. Stetler, Jas. Tyson, Philadelphia co.; Isaac N. Kerlin, Delaware co.

Delegates to American Medical Association—Drs. W. Varian, Crawford county; Amos Seip, Northampton; Jacob Day, York; A. F. Bilmer, Jefferson; J. L. Crawford, Indiana; Jos. Swartz, Perry; H. St. Clair Ash, Philadelphia; A. S. Bonsteel, Erie; T. J. Gallaher, Allegheny; J. W. Fulton, Chester; Wm. Compton, Lancaster; J. D. B. Kuhn, Berks; J. Curwen, Dauphin; M. H. Alter, Armstrong; J. Pursell, Montour; A. M. Pollock, Allegheny; H. Jennings, Tioga; Boyd Emory, Sr., Washington; W. B. Ulrich, Delaware; H. M. Nipple, Snyder.

Judicial Council.—For one year.—J. L. Stewart, Erie county; Jno. H. Packard, Philadelphia; Wm. Anderson, Armstrong. *For two years.*—Wm. Varian, Crawford county; Thos. Lyon, Lycoming; R. B Mowry, Allegheny. *For three years.*—Traill Green, Northampton county; H. L. Orth, Dauphin; Jno. T. Carpenter, Schuylkill.

Delegates to the New Jersey State Medical Society.—George D. Nutt, Lycoming county; Chas. S. Turnbull, Philadelphia; J. H. B. Amick, Schuylkill; S. S. Schultz, Montgomery; L. Lenker, Columbia; Chas. K. Mills, Henry Leffman, Philadelphia.

Delegates to the New York State Medical Society.—J. L. Stewart, Erie county; J. C. Elliott, McKean; B. F. Herr, Lancaster; A. H. Smith, Philadelphia.

Delegates to the Ohio State Medical Society.—Drs. J. M. Batten, Allegheny county; J. T. Clark, Erie; E. E. Montgomery, Philadelphia; W. H. Stewart, Armstrong.

Delegates to the Delaware Medical Society.—Drs. James B. Eby, Perry county; W. R. Findley, Blair; Geo. W. Vogler, Philadelphia; C. A. Woodward, Chester.

Delegates to the West Virginia State Medical Society.—Drs. J. A. Patterson, Washington county; D. W. McConaughy, Westmoreland; H. Howard Hill, Bedford.

Delegates to the Maryland State Medical Society.—Drs. Sam'l J. Rouse, York county; G. W. Berntheisel, Lancaster; Jno. Montgomery, Franklin; A. S. Brubaker, Lancaster.

Delegates to the Massachusetts State Medical Society.—Drs. L. Turnbull, Philadelphia county; H. Corson, Montgomery; Ellwood Harvey, Delaware; F. G. Albright, Lancaster.

No change was made in the Censors, save in the fourth district, where J. Montgomery Dea ver was made Censor, in place of Brainard Leaman; in the sixth district, A. B. Brumbaugh, Huntingdon co., in place of D. P. Miller; in the seventh district, M. H. Alter, of Armstrong co., was an addition; in the tenth district, O S. Wright, of McKean co., in place of T. J. Young.

On motion of Dr. Traill Green, the report was received and adopted.

Dr. R. L. Sibbett, of Carlisle, presented and read the "Report on Medical Legislation." It contained a résumé of acts of legislation already passed in the interest of medicine, and the draft of a proposed act compelling all practitioners to be registered. The report pays a high compliment to the Philadelphia *Record* for the energy, zeal and success with which it had hunted down, exposed and brought to justice, issuers of bogus medical diplomas. The physicians now in the Legislature, together with some ex-members, and other distinguished physicians, were also highly commended for their labors.

Dr. Jacob Price offered the following resolution, which was passed unanimously:—

"*Resolved*, That the thanks of the Medical Society of the State of Pennsylvania are hereby tendered to the editor of the *Daily Record*, of Philadelphia, for his untiring and most successful efforts in exposing and bringing to justice those who have been engaged in manufacturing and disposing of bogus medical diplomas."

The annual report of Treasurer Lee was read and referred to an auditing committee, consisting of Drs. Ehler, Curwen and Stewart.

Dr. Lee presented a brief report from the committee on plumbing and drainage, and the committee was discharged.

Dr. R. G. Curtin, of Philadelphia, read a paper on "Catarrhal Inflammation of the Pancreas," and Dr. I. N. Snively, of Franklin county, a paper on "Hygiene in its relations to the medical profession." Both papers were referred.

Dr. O. H. Allis, of Philadelphia, read a paper on "Why deformity so frequently follows fracture at the lower end of the humerus," and "Why fractures just above or below the knee are so dangerous." The Doctor illustrated his remark by taking off his coat and showing his own arms—the right one being sound and shapely, and the other a good deal deformed by a fracture of the elbow joint. He animadverted on the misuse by surgeons of right-angled splints in such fractures, and recommended that the broken arm be bandaged without splints and at full length, instead of being folded across the breast, as is so frequently done, and from which practice anchylosis so frequently results. The great danger from fracture above or below the knee, or from dislocation of the knee joint, is hemorrhage, caused by the rupture of the arteries, which at that joint come close to the bones and almost envelop them. Dr. Allis illustrated his remarks by a model of the bones of the arm, and diagrams of the bones and arteries of the leg.

Drs. Varian and Atlee discussed the subject at some length, and in the main agreed with Dr. Allis. Dr. Atlee, however, asserted that Dr. Allis's mode of treatment was not new; that as long ago as the days of Dr. Physick and Dr. Dorsey, substantially the same practice was followed.

Dr. O'Neal would hesitate to adopt Dr. Allis's treatment, for fear that anchylosis and damages for a stiff joint might be the result.

Dr. Ulrich defended Dr. Allis's practice, and so did President Carpenter, who had treated suc-

cessfully several cases of fracture of the elbow by bandaging the arm in an extended position and without splints. He had passed some of his patients among members of this Society, and so complete had been the cure that they could not discover which of the arms had been fractured.

Dr. Allis concluded the discussion by saying that he had very carefully read Dorsey's surgery, referred to by Dr. Atlee, and would like every member of the Society to read it and see wherein the treatment of fractures by that author accorded with or differed from his own.

After which, the paper was referred.

Dr. Traill Green offered the following preamble and resolution, which were adopted:—

"WHEREAS, a bill is now before the Legislature of Pennsylvania, the object of which is the erection, on the grounds of the Pennsylvania institution for feeble-minded children, of two additional buildings, for an asylum or hospital branch, thereby providing means for the better classification of the several grades of mental infirmity treated in that institution, and,

"WHEREAS, the institution in Delaware county represents the only provision made in the State for a class of defective persons as numerous as the insane, and who had been found amenable to modern means of improvement, therefore,

"*Resolved*, That the Medical Society of the State of Pennsylvania, assembled this day at Lancaster, commends the objects of the said bill, and hereby expresses its sympathy with all measures for the scientific care and training of the idiotic and feeble-minded children of this commonwealth, and hereby presents it as a subject that shall receive the enlightened attention of State authorities."

Dr. Ulrich suggested that this act be forwarded immediately to the representatives of Delaware county, which was agreed to.

Dr. James Tyson, of Philadelphia, read a paper treating of Bright's disease of the kidneys, and exhibited specimens of urine containing albumen. The paper was referred.

On motion of Dr. Ulrich, it was ordered that hereafter the transactions of the Society shall be bound in cloth.

Adjourned.

Third Day.

The Society was called to order by Dr. Carpenter, President, and Rev. Dr. Greenwald offered prayer.

By request of Dr. A. P. Carr, of St. Clair, Dr. Atkinson, Secretary, read the following letter:—

POTTSVILLE, May 10th, 1881.

Dr. Wm. B. Atkinson, Secretary of State Medical Society:

DEAR SIR: At a special meeting of the Schuylkill County Medical Society, held this day, it was unanimously resolved, that no medical paper presented by Dr. A. P. Carr should be received as a part of the annual report of this Society for 1881, to the State Society, and that the officers of this Society give this notification to the Committee of Publication.

S. C. SPALDING, M.D., *President.*

Attest: R. S. CHRISMAN, *Secretary.*

Dr. Varian asked that Dr. Carpenter, of that county, state how the matter was.

Vice President, Dr. Varian in the chair. Dr. Carpenter stated his knowledge of the matter.

Dr. Amick, of the same Society, made a statement.

Dr Cohen moved that the Committee of Publication be directed to refer the whole matter to the Censors of that district. After some discussion, on motion of Dr. Weidman, of Pottsville, the matter was referred to the Schuylkill county Medical Society.

After some discussion, Dr. Roland, of York, suggested, and Dr. Cohen made a motion, that hereafter a stenographic report of the discussions be taken, as these discussions are often equally as valuable as the papers read. The motion was agreed to.

Dr. L. Turnbull, of Philadelphia, read a paper on "Defective Hearing of Locomotive Engineers." The lecturer noticed at length many accidents occurring from this defect. The paper was referred.

On motion, a committee, to be of Dr. Turnbull's own choosing, was ordered, to bring the matter to the attention of the railroad authorities, and to prepare a memorial to the State Legislature to enact necessary laws relating to the matter.

Dr. J. Solis Cohen, of Philadelphia, read the "Address in Medicine:"—

In preparing this address on medicine, which I have the honor to read before you, I have watched, during the past year, the action of some little known or little used remedies, which have been recently brought into somewhat prominent notice, and the practical value of which is of some importance to medicine, should the claims advanced in their behalf prove well founded.

Perhaps there is no one remedial agent to which recourse is had more frequently or more confidently than to opium. * * * * Substitutes for opium are usually introduced to take its place in the production of some particular effect, rather than all. The most recent candidate for professional recognition in this connection is *piscidia erythrina*, the Jamaica dogwood, whose claims are sufficiently interesting to have induced me to test its value in the few suitable cases which presented themselves in my hospital practice, both at the Jefferson Medical College Hospital and the German Hospital, of Philadelphia. It is claimed for this drug that it is capable of soothing pain, without unpleasant sequelæ such as follow the use of opium. It is said to have been used for a long period in the rivers of Florida, for the purpose of catching fish; stunning the strong ones and killing the feeble. That the drug possesses considerable power in soothing pain, I have had sufficient evidence, but its liability to produce sudden collapse, from relaxation of the heart muscle, renders it anything but a safe remedy in continuous doses in private practice. Notes of a few cases, prepared for me by the residents on duty, are herewith appended. * * * * These cases will appear in detail in the Transactions. While exhibiting a remarkable hypnotic effect of the drug, when given in decided doses at short intervals, they exemplify a pernicious influence, carefully kept in the background, or ignored altogether by most of its advocates.

Several cases were narrated, illustrating the diuretic virtues of *Citrate of Caffein*, and in which there was a lack of that peculiar rigidity of the cardiac muscle to which attention has been called by British practitioners as a result of the use of this drug.

Attention was called to the successful use of *salicylate of cinchonidia* in vague rheumatoid neuralgias. It is best administered in pill, the dose being two to five grains, three or four times a day. It has been used extensively in the Throat room of the Jefferson Medical College Hospital, as a tonic in rheumatic sore throats and in diseases of the nasal passages generally, in that class of cases frequenting a public clinic and apt to be due to exposures similar to those which produce the rheumatic affections alluded to. The Doctor had also used it with considerable success and great satisfaction in several hospital cases of acute rheumatism, substituted for salicylic acid as soon as the latter had relieved the pain. The plan had been to give the salicylate of cinchonidia in five-grain doses at intervals of four hours, and to continue it, the patient remaining recumbent in bed, until all danger of cardiac complications was over.

Other salicylates were highly spoken of, and reference was made to the good effects of *chloride of calcium* in phthisis and infantile scrofula. As is well known, this practice is but the return to the use of a drug formerly employed as an alterant in the treatment of scrofula, before it became superseded by the use of iodine and its compounds.

Any remedial agent which, on scientific grounds or extensive empiric experience, promises success in the management of diphtheria, is worthy our respectful consideration. The false membrane is sometimes detached, by excessive secretion, from the underlying mucous membrane, and sometimes by a process of actual suppuration. The incontestible value of inspiration of the vapor of hot water in detaching the pseudo-membrane, has been accounted for by Prof. Oertel, on the ground that it produces a suppurative inflammation of the mucous membrane, and that the pus detaches the false membrane. Dr. Cohen's own opinion has long been that the vapor of water becomes insinuated beneath the irregular, and perhaps partially detached edges of the membranous patch, and thus mechanically lifts it from its seat. The well-acknowledged value of jaborandi in stimulating secretion from the surfaces of the mucous membranes, especially those of the mouth and throat, has led to the utilization of this drug in the form of its alkaloid, pilocarpin, for the production of a similar influence beneath the pseudo membrane, and thus to aid in its detachment and expectoration. Dr. Cohen gave some of the published results of the use of this drug, favorable and unfavorable, and expressed the belief that it is being recommended on one-sided theoretic grounds only, its depressing influence on the heart being kept out of sight; an influence which, on theoretic grounds, likewise, has thus far deterred him from prescribing it in his own cases.

The address concluded with a reference to the asserted value of *Iodine* in miasmatic affections as a substitute for quinia, and suggested that the members of the Society should give this reputed influence a severe test.

The paper was discussed by Drs. French, Townsend, of N. J.; Vogler, Tyson, Turnbull, Traill Green, Rahter, Atlee, and President Carpenter, and referred.

Dr. Crawford Irwin, of Blair county, read a paper on the "Scarlet Fever Epidemic of Hollidaysburg." A discussion followed, participated in by Dr. Traill Green (who denied the usual belief that this, or any other disease, was carried by physicians from patient to patient. He regarded these widely-separated cases as the result of different epidemic centres), Dr. Ulrich, Dr. Rahter, Dr. Atkinson (who urged upon his hearers the great value of the treatment by free ventilation, good nursing, and the employment of digitalis in positive doses. He explained his method of employing this article (of which we have given a very full report in this journal, see Vol. xliii, No. 23, 1880), and denied the danger, so much feared, of its cumulative effects), Dr. Pearson, and others, and was referred.

Dr. R. H. Milner, of Delaware county, was on the programme to read a paper on "Parasites of the Human Body," but as he was in bad voice his paper was read by Dr. Ulrich. The paper treated almost exclusively of trichina, the modes of its introduction, and the means of killing it and saving those affected by it

Drs. Ulrich, Leffman, Seiler, Varian, and others followed with some remarks on the same subject. Drs. Leffman and Seiler taking the ground that the hog is not responsible for all the blame cast upon him, and that men are frequently infected with the trichina from eating uncooked or partly cooked beef and other meats; and Dr. Varian believed that the parasite was often introduced into the human body by physicians feeding debilitated patients on raw or partly cooked meats.

Dr. Carl Seiler, of Philadelphia, read a paper on chronic laryngitis. He first considered the causes of this common affection, which he designated as a disease of civilization, and named among them impure air, deranged digestion, and the inhalation of irritating dust. He next described the symptoms and the appearances of the different parts of the larynx, as seen in the laryngeal mirror, without which, he said, the diagnosis could not be made, and stated that in most cases of chronic catarrhal laryngitis a fissure, abrasion, or ulcer was seen in the inter-arytenoid space, which gives rise to the cough and hoarseness. A brief outline of the proper treatment for the affection was then given by the author, and it was insisted upon that general systemic treatment alone, without the aid of topical applications to the larynx itself, was of little value, and that patients, even when sent to a warm climate during the winter were not benefited, but that if they received local treatment made a rapid recovery, more rapid than could be expected in the cold and changeable climate of this section of the country.

Dr. J. L. Crawford, of Indiana county, read a paper on "Indications calling for active treatment in Typhoid Fever." He recommended that active treatment should be only used when

the temperature of the patient rises to 103 or over. In such cases the cold bath and quinine are recommended in preference to all other remedies, and when debilitated the patient should have alcoholic stimulants.

Each paper was respectively referred to the Committee of Publication.

Adjourned until afternoon.

AFTERNOON SESSION.

The President called the Society to order at 2 P.M.

Dr. S. T. Davis, of Lancaster, read the Address in Obstetrics, reviewing the work done by his predecessors. He gave a detailed account of opening the abdominal cavity, as performed by Dr. Richardson, of Philadelphia, to remove the pregnant uterus and ovaries in a dwarf; in a case of abdominal pregnancy, by Dr. H. P. C. Wilson, of Baltimore; a case of puerperal laparotomy, for rupture of the uterus, by Dr. J. W. McCormack, of Bowling Green, Ky., and of a similar case in his own practice.

He discussed the subject of oophorectomy for dysmenorrhœa, epilepsy and insanity; of puerperal pyæmia, of laceration of the perineum, and alluded to the views of Dr. B. E. Mossman, of Greenville, Pa., who regards dilatation as a preventive of laceration, as quoted in his paper in the *American Journal of Obstetrics*, July, 1880. In conclusion, he alluded to the work of the Section on Obstetrics of the American Medical Association, at its late session in Richmond. The paper was referred.

Dr. R. J. Levis, of Philadelphia, presented his method of treating hydrocele and cystic tumors in general, by injections with carbolic acid.

The treatment of hydrocele by producing suppuration has generally been abandoned as prolonged, painful and dangerous. The object of the operative procedure now employed is to produce a plastic grade of inflammation and adhesion of the walls of the cyst.

For this purpose the tincture of iodine has been most frequently used, but its action is uncertain, painful, and sometimes, uncontrollable. It is claimed that carbolic acid produces an inflammation, which neither falls short of, nor exceeds in intensity, that of plastic exudation.

Dr. Levis has relied exclusively on this treatment in the Pennsylvania Hospital, in the Jefferson College Hospital and in private surgical practice, since the year 1871, and has never failed in curing hydrocele of the vaginal tunic of the testis, and many serous, mucous, and synovial cysts in various parts of the body.

After the usual tapping, pure carbolic acid, liquefied by a five or ten per centum addition of water or glycerin, is injected by a syringe with a long nozzle, reaching entirely through the cannula. There should be no more dilution than is necessary to liquefy the crystals. The carbolic acid is then, by manipulating the scrotum, diffused over the cyst walls. No pain is produced by the injection, and the patient is permitted to walk about and to attend to his ordinary duties until generally the next day, when inflammation renders rest agreeable to him. The amount injected is from forty to ninety grains, according to the size of the cyst. No general toxic effects from the absorption of carbolic acid have ever been noticed. It is believed that the immediate effect of pure carbolic acid on surfaces secreting albuminous fluids is to seal them, and by the occluding action prevent absorption.

It is claimed that in carbolic acid we have a means, if properly used, of producing almost uniformly the proper plastic degree of inflammation necessary for the radical cure of hydrocele and other serous cysts, which are usually deemed amenable to treatment on such principles.

This was referred.

Dr. Risley presented, by title, his report on "Weak Eyes in the Public Schools of Philadelphia." This report was read by title only, for the reason that the twenty minutes allotted, under the rules of the Society, were not sufficient for its presentation. The extensive observation and peculiar character of this paper forbids any brief abstract of its contents, but it will, in due time, appear in the volume of the transactions of the Society.

The President appointed the following:—

To make the Address in Medicine—Dr. E. R. Mayer, Wilkesbarre. In Surgery, Dr. H. L. Orth, Harrisburg. In Obstetrics, Dr. R. S. Sutton, Pittsburg. In Hygiene, Dr. B. F. Muhlenberg, Reading. In Mental Disorders, Dr. C. K. Mills, Philadelphia.

Several invitations were read by the Chairman of the Committee of Arrangements, which were accepted and thanks returned.

Dr. W. S. Roland, of York, offered the following, which was adopted:—

Resolved, That the Secretaries of the several County Societies in the State shall, within three months after the passage of this resolution, report to the Secretary of the State Society the number of students of medicine under tuition of members in their respective Societies during the year ending May 1, 1881, and the number that appeared before the Medical Examiners for examination during the same time; and that said reports shall be presented in the next Transactions of the State Society.

The Secretary read a communication from the American Public Health Association, relative to vaccination, which, on motion, was ordered to be entered upon the minutes.

On motion of Dr. Atkinson, the Standing Committee, which no longer had any duty to perform, was abolished.

Drs. M. S. French and John L. Atlee were appointed by the President to conduct the President-elect to the chair.

Dr. J. L. Ziegler, in taking the chair, thanked the members, and hoped for a full attendance at the next session.

Dr. J. T. Carpenter, on behalf of the Schuylkill County Medical Society, presented a handsome gavel to the State Medical Society.

Dr. Ziegler received it, with appropriate remarks.

Thanks were then tendered to the retiring President, and to the profession and citizens of Lancaster, for their courtesies, and the Society adjourned to meet in Titusville, on the second Wednesday in May, 1882.

Therapeutic Uses of Pilocarpin.

The London *Medical Record*, March 15th, gives further notices of the use of this alkaloid. Dr. Lax, of Berlin, following Guttmann, has employed muriate of pilocarpin in a small epidemic of diphtheria, and has obtained results so far beyond his most favorable anticipation, that he thinks himself obliged to recommend it most earnestly for wider use. Between September 24th and November 17th, he treated for diphtheria sixteen children of various ages, from one to sixteen years. The first six children were treated by penciling with a 4 per cent. solution of nitrate of silver, and a solution of chlorate of potash as a gargle. To two quite young children, a mixture of chlorate of potash was given. Of the six children four recovered quickly, while two, whose cases were very severe, died. In the last ten cases occurring after October 5th, Lax employed exclusively the muriate of pilocarpin. Six of these were very severe, and in two of them death was expected every night. Nevertheless, all these children treated with pilocarpin entirely recovered. An increased secretion of mucus and saliva occurred, and great masses of diphtheritic effusion were expelled from the mouth as well as from the nose. The breathing became freer, *râles* ceased to be heard, the fever passed away, and the appetite recovered. The children generally recovered in from three to five days. Labial herpes indicated the favorable processes in all cases. On the third day already all trace of the deposit on the soft palate and tonsils was removed. According to the age, Lax prescribed two to four centigrams of muriate of pilocarpin, sixty to eighty centigrams of pepsin, with two to three drops of hydrochloric acid in seventy grams of distilled water, giving every hour from one teaspoonful to one tablespoonful. In addition, Tokay wine was given hourly (a teaspoonful to a tablespoonful), and warm packs were applied to the neck.

M. Vulpian, having arrived at the conclusion that catarrhal inflammation of the respiratory tubes, and inflammation of the serous membranes in their first stage, are those in which jaborandi or its alkaloid pilocarpin have the most incontestible use, M. Tauleigne states, in his graduation thesis on the subject, that he has employed them in a series of cases, of which he relates fifteen. The effect of jaborandi or pilocarpin is most prompt, and its success most evident, at the outset of the disease. A single effusion of four grams (one drachm) of leaves of jaborandi is often enough to get rid of the affection; and M. Vulpian cites a case of well-marked pleurisy in a child, aged ten years, which, treated from the outset, yielded to the action of pilocarpin in two days. Much less is to be expected from its use in long standing cases. The author relates from his observation of pleuritic effusion without fever or inflammation, in which jaborandi has given good results, one case, in which considerable effusion had for a month resisted the use of tincture of iodine, eight large blisters, and diuretics, and yielded in seven days to two doses of jaborandi. The fluid once absorbed, and pleuritic rubbing having been noted, jaborandi becomes useless. Recourse must then be had to tonics, and the application of tincture of iodine. Pilocarpin is indicated in the various forms of bronchitis. The author relates a remarkable case of chronic bronchitis, which had persisted during four years, with continued cough, difficulty of breathing, and suffocation, which recovered after the administration of two draughts containing four centigrams of nitrate of pilocarpin. As to the mode of administration he recommends the hypodermic injection of the nitrate of pilocarpin, in doses of one centigram. The patient should be fasting, without which the medicine is apt to provoke nausea and vomiting, as soon as sweating is established. In constipated subjects it acts badly, and it is necessary to give a preliminary purge.

Treatment of Valvular Disease of the Heart in Children.

In an article in the London *Med. Press and Circular*, Dr. W. H. Day writes on this subject:—

The symptoms which arise as a consequence of these organic changes are best relieved by rest and the avoidance of exercise and excitement. By maintaining the general strength and guarding against local congestions and inflammatory attacks, we may often succeed in giving a fair share of health and comfort to children, while warm clothing (particularly cotton-wool or flannel worn over the chest), nutritious food, and active aperients will tend to keep in check some of the worst symptoms, as dropsy, when they show themselves. If congestion of the lungs or bronchitis occur, squill, carbonate of ammonia, belladonna, strychnia, and other stimulating expectorants and sinapisms will be indicated.

When the heart is getting weak and quick, in mitral disease, and there is a tendency to dilatation of the right cavities, the tincture of digitalis administered in gradually increasing doses will improve the tone and fullness of the pulse beat, reduce the frequency of the heart's action, and cause the over-distended cavities to contract more vigorously on their contents. Instead, therefore, of blood accumulating in the heart during diastole, a larger quantity is expelled at each contraction of the ventricle. Digitalis has been said to increase the discharge of urine, but there is some doubt about this so long as low arterial tension remains unaffected. I carefully measured the quantity passed in two cases of mitral regurgitation in children with dilatation of the right ventricle, yet in neither was there any appreciable difference in the amount passed, nor any change in its quality. They were in no way improved by the drug. Traube first noticed that

the fall of the pulse rate and the rise of arterial tension during the employment of digitalis are attended with an increased amount of urine.

In nearly all the cases in which I have given digitalis for the heart affections of children, I have combined it with iron, and frequently with strychnia also. Iron improves the quality of the blood, and the muscular power of the heart. Digitalis is of most value in simple dilatation from debility in the cardiac muscle, and in both forms of mitral disease, where weakness and irregularity of the pulse are present. It may be given with advantage in dilatation with hypertrophy, but not in the latter form of heart affection alone. If nausea, headache, or unsteadiness of pulse should come on during the employment of digitalis, the drug should be intermitted for awhile.

In certain rickety children with thoracic deformity, with twisting of the aorta, hypertrophy of the left ventricle is early developed (Rokitansky), and in some cases even valvular disease (Hilton Fagge). In these cases cardiac failure is early developed.

Heart cough is common in adults in the failing stages of heart disease, and is usually found in children with heart disease at any stage. It is the result of congestion of the pulmonic circulation; it is aggravated by sedatives, like paregoric, and even by bromide of potassium; it is effectually relieved by cardiac tonics, like digitalis combined with iron.

Treatment of Endocarditis in Children.

In an article on this disease, in the London *Medical Press and Circular*, January 12, Dr. W. H. Day, Physician to the Samaritan Hospital for Children, writes:—

The treatment should in some measure depend upon the disease with which the cardiac affection is complicated, and seeing that it may arise in the course of acute rheumatism, or scarlet fever, it will be important to modify the treatment accordingly. The treatment is really the same as that of pericarditis, with which it is often associated, but there is this difference: endocarditis speedily tends to exhaustion, and is not so amenable to active measures. The patient should remain in bed for a length of time after the acute stage has passed over, so that excitement may be diminished, and the effects of strain should be kept off the injured valves by lowering the blood pressure, as far as possible. This is recommended by Dr. Milner Fothergill, in a lecture, in the *Medical Times and Gazette*. September, 1878. "This fact, then, is ascertained and confirmed by experience, viz., that the damage done to the endocardium by rheumatic inflammation may abide for four or five years without producing any conscious detriment to the health or well-being of the patient, or (as far as we have the means of judging) any further injury to the structure of the heart. And it is a most important and consolatory fact. But in other instances other results immediately follow. When after its departure acute rheumatism leaves the endocardial murmur behind it, which, though known only to the physician, is the sure sign of injury done to the endocardium, it leaves it attended from the beginning with other symptoms, which the patient is sufficiently conscious of, and these are directly referable to the heart. They consist of palpitation, pains, and dyspnœa, which are not constantly present, but only under bodily exertion and mental excitement. The child who has had the præcordial murmur ever since it suffered a certain rheumatic attack, is just the same child as it was before, except that it cannot join in any pastime requiring rapid movement; for then its heart palpitates, it loses its breath, and is obliged to sit down. Men, too, are just the same men as they were before, only perhaps they cannot run up stairs without panting and hurry, and they constantly find themselves obliged to restrain their bodily efforts within certain limits, and to beware of mental excitement, for fear of palpitation and dyspnœa.

Preparation and Uses of Benzoate of Calcium.

Mr. Jas. T. Shinn gives directions for the preparation of this salt in the *American Journal of Pharmacy*, April, 1881:—

The proportions of benzoic acid and calcium in the benzoate are 113 to 20, or of the crystallized acid and carbonate of calcium, 122 to 50. Hence the following formula for its manufacture:—

℞. Benzoic acid, ℥ iv gr. xxxij (1952 grs.)
Calcium carb., ℥ j ʒ v ℈ j (800 grs.)
Boiling water, Oiv or q. s.

Mix the acid and precipitated chalk thoroughly, in a large mortar, and add water gradually to allow most of the carbonic acid gas to escape and prevent frothing over of the liquid. When the combination has taken place, or nearly so, the mass is transferred to a porcelain dish and dissolved in the remainder of the boiling water, with the exception of a slight excess of carbonate of calcium. Filter, while hot, into a shallow dish, when crystals will form on cooling. The mother liquors may be evaporated twice more and yield more crystals, the whole product being about ℥ iv, ʒ v.

The salt is in feathery crystals, of a silky lustre, odorless, with but slight, rather alkaline, taste, and is soluble in about 24 parts of water. It may be dispensed either in capsules or solution, a very good form of the latter being:—

℞. Calcii benzoat., gr. cxxviij
Aquæ destillat., fl. ℥ vj
Syr. aurantii, fl. ℥ ij. M.
Ft. mist.

This makes a solution, by the aid of heat, containing eight grains to half a fluidounce, which is the usual dose.

At a meeting of the Philadelphia County Medical Society, Drs. A. H. Smith and O'Hara spoke of the great benefit this preparation had been in cases of albuminuria during pregnancy, and, as the salt may be called for and is not on the price lists of the chemists, the above formula for its preparation may be useful. The first crop of crystals can be taken out and dried on bibulous paper within an hour of the receipt of the prescription by the apothecary.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1 60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3 20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER-GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE IMPROVEMENT OF TEMPERANCE DRINKS.

Scarcely any subject of general sanitary science more deserves the attention of those interested in elevating the race than the temperance movement. The ravages of alcohol are annually becoming more apparent, as its use extends. The cheapness of distilled liquors of the baser sorts leads to their introduction into wine growing countries; even the peasantry of Italy and the South of France are becoming spirit drinkers. As for England, the abundance of spirits, beers and ales consumed there, surpasses belief.

This was illustrated at St. George's Hospital, London, recently. A committee was appointed to inquire into the drinking habits of the patients at that and other London hospitals. Their report is quite a revelation of the previous drinking habits of the patients. In the twelve hospitals only one total abstainer was discovered. The daily practice of many of the others is almost incredible to quiet people, who take their one or two glasses daily, and are sometimes made to feel themselves miserable sinners for doing that. The following are some of the instances recorded by the committee, showing what had been the daily consumption, previous to admission, of certain patients: Three or four pints of beer, and two glasses of whisky (age 53): four or five pints of beer, with frequent excesses (age 59); ten pints of beer, and ten glasses of whisky (age 23); hard drinker, chiefly of rum (age 30); indulged in great excesses, often drink two bottles of brandy a day (age 43); eight pints of beer daily (age 42); four pints of beer, with excesses (age 38); eight pints of beer daily (age 42); five pints of beer, with excesses (age 38); three glasses of whisky (age 34); from three to four pints of beer, and from one to twelve glasses of rum (age 54); seven pints of beer, and seven glasses of spirits (age 41); drunk three times a week (age 36); a confirmed drunkard (age 33); immense quantities of whisky (age 45); twelve to fourteen pints of beer, and a variable amount of rum (age 31); ten pints of beer, and a pint and a half of rum (age 45); the largest consumer of beer "never exceeded" twenty-six pints a

day (age 35); the largest consumer of spirits took twenty to thirty glasses of gin daily (age 30).

What health can be expected of a population who indulge in this manner?

The remedies which have been suggested are: 1, absolute prohibition of alcoholics; 2, the fostering of temperance by increasing the cheapness of light beers and wines; 3, the substitution of other beverages not containing alcohol.

The first method has proved a failure wherever tried on any extended scale; the second is deceptive; the third is probably that which promises the most. The establishment of coffee taverns, holly tree inns and shops where "temperance drinks" are sold, has unquestionably done vast good, and is capable of wide dissemination.

A great deal of the drinking habit comes from a desire to quench the thirst, or to have a slight stimulant. Nothing of this kind is so cheap, so effective, and so easily obtained in most localities as an alcoholic beverage. Yet a cup of tea or coffee, or a glass of aerated water containing a pleasant carminative, would be equally grateful, and, if well made, in many cases just as popular, or more so.

Hence the manufacture of temperance drinks should be encouraged as much as possible. Unfortunately they are generally so vilely prepared or so deliberately fraudulent that they offer little enouragement to the consumer to repeat his experiment with them. An instance was recorded last summer, by one of the English government analysts. He examined nine samples of so-called unfermented wines. Of these nine, three, bearing labels stating that the bottle contained "pure grape juice," "virgin fruit of the vine," etc., consisted of sugar, tartaric acid, salicylic acid, and coloring matter, with a considerable quantity of copper, the result, doubtless, of ignorant or careless manufacture. Grape juice was entirely absent. Another sample, labeled "Pure and genuine unfermented fruit of the vine," was evidently a composite article artificially made, and so carelessly prepared as to contain alcohol. One sample of unfermented wine imported from abroad contained some grape juice; but the presence of alcohol and an abundance of yeast cells showed that fermentation had not been arrested. One example was labeled "The selected wine of the Temperance Fraternity." This was an ordinary low class fermented wine, containing a large amount of alcohol. Of the nine samples of the so-called unfermented wines, only one was genuine and was what it professed to be, "Pure grape juice, entirely free from alcohol."

In France, enormous quantities of aerated water, under the name of *Eau de Seltz*, is used. Last summer, the Paris papers made the discovery that it was prepared from common, dirty Seine water, and various cases of typhoid fever were supposed to have been traced to its consumption. It was also said to have lead in it, and an analysis supporting this statement was presented to the Academy of Sciences. It appears that the Paris hospitals alone consumed 150,000 bottles of this water annually, and this is considered evidence in favor of its salubrity.

The "ginger ale" imported from Dublin to this country is deservedly popular, but our own manufacturers are satisfied by a most wretched imitation, in which ginger is replaced by red pepper! In an English work, recently published, for the benefit of druggists and aerated water manufacturers, full directions for falsifying and adulterating are given. In order to produce a fine foam and a highly aerated appearance, infusion of senega is recommended; lemonade syrup is made from the real or imitated oil of lemon in syrup; and flavoring materials are very often taken from a widely different source than their names denote.

The American soda water fountain is an excellent institution when well conducted; but the flavoring syrups used are often fraudulent, and not rarely of doubtful healthfulness. We have heard of various persons who were made sick by free indulgence in them.

While, therefore, we look upon the introduction of cheap, palatable and healthy temperance drinks as one of the most active agents in persuading people to cease beer and spirit tippling, we must deplore the commercial greed which depreciates their character and practically bars their general use. Here is a field in which

workers in the cause of temperance can display their energies to good effect.

Notes and Comments.

Salt Water in the Treatment of Sores and Purulent Collections.

The Paris *Médicale* publishes an interesting paper on this question, which concludes as follows:—

Salt water injected in purulent collections, or used in the dressing of sores, exerts a complicated action, because of its density, its antiseptic properties, and its general effect upon nutrition. Its antiseptic properties have been fully set forth by our experiments on the globules found in blood and pus. Salt is a preserver of meats, and arrests the progress of decomposition in organic substances. According to Cyr, "chloride of sodium acting as a solvent for caseine and albumen, contributes with this last in preventing the deformation and dissolution of blood globules."

A remarkable property of salt water is, that it destroys, hence removes, the fetor exhaled by gangrenous sores. We have often noticed this disinfecting effect, especially in a case of diffused anthrax on the neck, during elimination of the eschars.

Its general effects upon nutrition have been ably described by Boussingault, Barbier, and Bérard. When a certain quantity of salt is mixed with the food of animals, they increase one-sixth in weight.

Man's sufferings are very great when deprived of salt. A Russian lord having, through avarice, deprived his vassals of this condiment, they all experienced gastric troubles; and during the siege of Metz, nothing so affected the besieged as when their salt rations were discontinued.

The saline substance is rapidly absorbed in the interior of purulent collections and on the surface of sores.

Patients under this mode of treatment react with great energy from very abundant suppurations, and they show signs of a rapid gain in flesh, and of perfect nutrition.

"Under the influence of salt water, the face, from being cadaverous, gradually assumes color, the tongue cleanses, appetite returns, thirst is reduced, and diarrhœa is checked. All the organs resume their normal functions."

Salt water, as a dressing for sores, has always been successful with us, either when applied to hasten cicatrization, or used for atonic sores on bones, or during the elimination of eschars. It has also been of service in affections of the bones having required scooping out or resections. When injected, it prevents the decomposition of pus within the structure of bones; and pledgets of lint saturated with it have soon started granulations, and hastened the formation of cicatricial tissues.

Treatment of Pyrosis.

M. Ory gives the following prescriptions in *la France Médicale:* of course the diet must be attended to; a milk or vegetable diet with alkaline drinks being beneficial. Jeannel recommends the following mixture:—

℞. Rhei pulv., ℥ ijss
Sodæ bicarb., ℥ ss
Syr. simp., f. ℥ v
Aq. menth. piperit., f. ℥ viij. M.
Sig.—Tablespoonful twice or four times daily.

The compound chalk powder containing canella and pepper is recommended by Bouchut in cases of pyrosis, accompanied by chronic diarrhœa.

The following powder has been prescribed with success:—

℞. Magnesiæ calcin. pulv., ℥ j
Sacch. alb. pulv., ℥ j
Bismuth. subnitr., ℥ j
Sodæ bicarb., ℥ iss. M.
Sig.—Ft. chart. No. xl. One just before meals.

Franck recommends—

℞. Magnesiæ carb., gr. xxx
Rhei pulv., gr. viiss
Canell. pulv., gr. ivss. M.
Sig.—For two powders.

Bouchardat considers the following powder useful in pyrosis:—

℞. Rhei pulv., ℥ ij–gr. xv
Magnesiæ calcin., ℥ ij–gr. xv
Opii pulv., gr. iss. M.
Sig.—Div. in chart. No. xv. One before meals.

Tonic Potions in Convalescence.

M. Audhoué recommends (*Therapeutic Contemporaine*), the two following potions, agreeable to take, during convalescence from grave maladies, fevers, etc.:—

℞. Cinchon. flav. pulv., ℥ j–gr. xv (5 grams)
Aquæ font., f. ℥ x (300 grams)
Pure milk, f. ℥ ij–℥ ij (70 grams)
Sacch. alb., ℥ v (20 grams).
Sig.—Boil the bark with the water, down to 100 grams (f. ℥ iij–℥ j), then let stand for twelve hours, strain, and add the milk and sugar.

This should be heated in the water bath and taken early in the morning; it has very little bitterness.

The second potion is similar, and prepared in the same manner, except that 20 grams (℥ v) of chocolate is dissolved in the milk before it is

added to the rest of the potion. These potions would prove much more agreeable to the convalescent than the bitter tonic mixtures in vogue.

Sulphate of Copper in Neuralgia.

It is stated in the "*Concours Médical*" that M. Féréol has met with additional success in his medication by the aid of sulphate of copper. He has somewhat modified his formula; no longer uses the liquid form, but gives the salt in the shape of a powder associated with subnitrate of bismuth, thus:—

Ammoniacal sulphate of copper,
2 centigrams (=grs. 0.30)
Subnitrate of bismuth, 25 centigrams (=grs. 3.75)
For one powder; make 10 similar powders.

Five of these powders are to be taken daily; two dissolved in a little water during each of the principal meals, and the fifth between meals, along with a cup of milk.

The advantage of this method is that the patient experiences less disgust, and is spared from a saburral condition of the mouth and a persistent, disagreeable copper taste.

Medical Treatment of Hemorrhoids.

Dr. T. V. Sabal gives the following formula: Reduce four grams (ʒj) of iodoform to a fine powder, in a mortar, and add to it:—

℞. Powdered opium, 75 centigrs., (gr.11.25)
Vaseline, 30 " (gr.4.50).

Sig.—Use as a local application morning and evening, after each alvine evacuation, care being taken first to wash with warm or cold water.

By adding four grams of tannin to this preparation the smell of iodoform will be reduced. The bowels are to be kept open with the following prescription:—

℞. Sulphate magnesia,
Carbonate magnesia,
Sulphur precipitate,
Sugar of milk, āā 15 grams (gr.225)
Powdered anis, 8 grams (f.ʒij). M.

Sig.—One or two teaspoonfuls of this powder in the evening, at bedtime.

A Tæniafuge.

A correspondent sends us the following formulæ:—

℞. Ungt. hyd., ʒss
Ol. filix mass., f.ʒj
Pulv. acacia, q. s.
Syrp. simp., f.ʒj. M.

Sig.—Take at one dose in the morning, and follow in two hours with:—

℞. Ol. ricin., f.ʒj
Ol. terebinthinæ, f.ʒj. M.

The above, he adds, has never failed, in my hands, to bring away the worm. In almost all instances the head the first time, as well as the body of the worm.

Correspondence.

What Constitutes a Poisonous Dose of Morphine?

Ed. Med. and Surg. Reporter:—

At eight A.M. on November 22d, 1880, I was hurriedly summoned to see Constable J. H. Rice, of this town. Upon arriving I found him in a state of death like stupor. Occasionally a short, jerked respiration, pulse not perceptible, with countenance suffused and livid. His wife said he had come home the previous evening and gone to bed at nine o'clock. At ten she was awakened by his heavy snoring, and after vain efforts to awaken him she became alarmed and sent for a physician. The doctor prescribed some simple remedy, telling them if he became able to swallow to give him some. Another one was then called, but nothing more was done.

Upon hearing her statement and sending a messenger for information, to the drug store, our suspicions were confirmed, and we ascertained that he had bought, and as he afterwards confessed, taken, fourteen grains of morphia sulphas. I immediately injected seven drops of fluid extract belladonna into his arm, and a strong decoction of coffee into the rectum, sent for solution of atropia (gr. j to ʒj.), and commenced artificial respiration.

About this time the two physicians who had been in during the night returned, and upon learning the cause of the trouble expressed their entire hopelessness of the case, in which I concurred. In fact, the man was apparently so near death that the other doctors, together with his wife, implored me desist from any further efforts at resuscitation, and let him die undisturbed. This, I was about to do, when his mother, in her frenzy, *ordered* me to continue my exertion.

I then injected thirty drops of the solution of atropia every fifteen minutes until the pupils dilated (120 drops). Then two grains of citrate caffeine, hypodermically, every hour; continued artificial respiration, strong coffee by rectum, to which was added, later in the day, milk and stimulants. Ice-water douches were applied to face and chest, together with warmth and rubbing to extremities, etc. In three hours after commencing this treatment his pulse was faintly discernible at about two hundred a minute, and respiration somewhat improved. From this on he made steady improvement, and more rapidly after electricity had been applied, until, at 5 P.M., nine hours after respiration was commenced, and twenty hours after the narcotic was taken, he could be so far aroused as to open his eyes and murmur incoherently, upon being raised up in bed and violently shaken. At twelve, midnight (twenty-seven hours after having taken the poison) he spoke plainly but incoherently, but the next morning was, in a measure, sensible. After a week of convalescence, the first half of which he slept almost all the time, he was able to be

around, and in a month had recovered his usual health.

There is no doubt about the quantity taken, as the druggist weighed it exactly, and the patient afterward confessed to taking it all, with suicidal intent. Also no vomiting or movement of the bowels took place until thirty-six hours after taking the poisonous dose, and he had never taken more than an ordinary dose before.

He is now in excellent health.

J. A. Kimmel, M.D.

Findlay, Ohio, May 8th, 1881.

Cupric Test Pellets.

Ed. Med. and Surg. Reporter:—

My attention has been recently called to an article in your journal on "Cupric Test Pellets," by Dr. Jos. S. Neff. In this article the doctor attributes the invention of these pellets to Dr. Pavy, who described them in the *British Medical Journal*, February 7, 1880, but who fails to give a formula for their preparation. Dr. Neff goes on to state that, appreciating "the great practical use of these pellets," he has had some prepared, but he also neglects to give the formula by which they may be made. Under these circumstances permit me to state that the idea of cupric test pellets arose, I think, with myself, and that I published in the New York *Medical Record*, March 23, 1878, page 228, the following:—

℞.	Sulphate of copper (ch. pure),	1 part
	Cryst. tart. of soda and potassa,	5 parts
	Sodic hydrate (ch. pure),	2 parts

Mix thoroughly in a mortar; the more labor spent on this the better the product. The result will be a pasty mass, which can be transferred to a wide-mouthed bottle and kept till wanted. To use it, take of the mass a piece about the size of a common cathartic pill, put it in a test tube, and add about two fluid drachms of water; boil till the mass is dissolved, and the solution has a uniform, pale and rather dirty blue color; then add two or three drops of the suspected urine and boil again for a moment. If sugar be present the usual reaction will be manifest."

H. G. Piffard, M.D.

Obscure Rubeola.

Ed. Med. and Surg. Reporter:—

I was considerably interested in Dr. E. R. Stone's communication in the Reporter of April 30th, and am induced by it to report a case.

On Friday, March 18th, a young merchant of this village came into my office to consult me about his mouth. On examination, I found the gums, throat and whole inside of the mouth red and inflamed; exactly resembling a bad case of mercurial poisoning. But a peculiarity was that the salivary glands were but little if at all affected. A few days before he had had a number of teeth plugged with an amalgam of mercury and tin, and I concluded that the source of the trouble was from the teeth, gave him potas. chlorate with hydrastis and sent him away.

In the evening he sent for me, when I found, in addition, an eruption all over the face, extending to the body, most prominent along the edges of the hair, exactly as described by Dr. Stone in the case of the married lady.

The eruption was "confluent, which, with the injection of the eyes, gave a decided bloated appearance. And the small round groups of papules at first glance looked uncomfortably like smallpox." I told him it looked suspicious; but it was the only symptom; there was little headache or backache, and but slight constitutional disturbance. What was it? At the time I was having a good deal of scarlet fever, and a few cases of measles. Thinking it would prove one or the other, I reserved my opinion. Saturday morning found the eruption had extended all over the body, clear to the extremities. There was no coryza, and the rash was not crescentic nor dark enough for measles. No, it was not measles.

It was not scarlet fever. The rash was not fine enough, and had not that scarlet look usual in that disease, and besides there was no sore throat nor disturbance of the stomach, and he was not much sick.

I was completely puzzled, and told him bluntly I had never seen a case like it, and did not know what to call it. Sunday he came to see me. The eruption had nearly disappeared, and he was feeling quite well. Monday he was attending to his regular business.

Shall we call it rœtheln? I send you this for my quota of the blunders in practice. Let us hear from others.

J. Hubbard, M.D.

Wauconda, Ills.

Venesection Again.

Ed. Med. and Surg. Reporter:—

Owing to an absence of a week, attending the meeting of the American Medical Association at Richmond, and constant professional engagements after my return, I did not take up my number of the Reporter of April 30th till to-day, when my eye caught the article of Dr. J. E. Stinson, of Montague, Texas, and I hasten to reply. I do not wish the Doctor to understand that I would favor the practice of blood-letting in all cases, nor in all the stages of pneumonia. I think that Dr. Corson's articles were plain enough, and I simply wrote believing that, in the class of cases which I had to deal with in this section of Connecticut they were treated *more* successfully by blood-letting in the first stage. Since reading that article, I have had thirteen cases, twelve of which were treated by blood-letting and recovered; one without, and it died. Of course, it takes more than one swallow to make a summer, but this is a better result than I ever got before, under any other treatment, and I have tried them *all*, in a large and active practice of eleven years. The Doctor says: "*Are the finger posts our fathers erected for our guidance lost?*" Let us see how this is. I read a paper before the Section of the Practice of Medicine, at the meeting of the American Medical Association, just ended at Richmond, on the same subject, which created a very animated discussion. Prof. S. D. Gross, of Philadelphia, Alfred C. Post, of New York city, Nathan S. Davis, of Chicago, Dr. Ballou, of Rhode

Island, all teachers, old men, men of large experience and reputation, *gave it as their testimony that since the decline of blood-letting they had observed an increase of mortality in pneumonia*; that their best successes were during the period of blood-letting; and strongly advocated its use in proper cases. Other gentlemen gave the same testimony publicly then, and any number of others, including Prof. L. A. Sayre, of New York city, came to me afterwards expressing the same opinion and thanking me for my paper, and the stand I had taken. Are these no landmarks? Is not the testimony sufficiently distinct for the Doctor, even with his bias, to read while he runs? Experience must be our guide, and my experience has certainly been very gratifying to myself and patients. WM. C. WILE, M.D.

Sandy Hook, Conn., May 25, 1881.

Poisoning by Carbolic Acid.

ED. MED. AND SURG. REPORTER:—

Many practitioners do not realize that carbolic acid is poisonous in a serious degree. I do, now. It came about in this way: A patient suffered from pin worms in the rectum. He was ordered a pretty strong solution of carbolic acid as an enema, with instructions to force it out immediately after its administration. That ends the first chapter.

I was not the medical attendant, but was sent for in a hurry, and found a man suffering from either obscure narcotic poisoning, or some brain trouble. I could not make anything of the case until I found out the following history: shortly before I was sent for he was found in a stupid state, in the water-closet, with an ℥ viij bottle containing some fluid smelling strongly of carbolic acid. His wife thought that he had used it as an injection. I forthwith washed out the rectum and colon as thoroughly as possible, with water, and found the evacuations to smell strongly of the acid. In half an hour consciousness returned and I found the facts substantially as stated.

He had used the enema as directed, but passed only a part of it. The balance remained and nearly caused fatal poisoning. I do not propose to burden this confession with the symptoms of carbolic acid poisoning.

The description given in *Ziemssen* might be applied to the case in nearly every particular. I did not find whether or not the worms suffered as severely as the patient.

The victim could not realize properly why he should pay me five dollars when he felt that he was the aggrieved party. I received the fee, under a mild protest, as I did not care to argue the *pros* and *cons* of the matter.

I have reported the case, for the reason that it may have passed from the mind of the regular attendant. K.

Treatment of Tænia.

ED. MED. AND SURG. REPORTER:—

Having had an opportunity of treating two or three cases of "tænia solium," I will offer the following simple treatment, for the expulsion of the troublesome vermin, although the small number of cases scarcely justifies its being reported:—

Some members of the profession may give it a trial, and if they have the same good effects from the remedy that I have had, I only hope that they will make the fact known through your valuable columns.

℞. Fl. ext. filicis mas. (pure), ℥ ij
Ol. terebinthinæ, ℥ j
Ol. ricini, ℥ ss
Mucilag. acaciæ, q.s. ut ft. emulsio, ℥ iv. M.

SIG.—Take one tablespoonful three times a day, for three days (on an empty stomach); begin again in a week or ten days, according to effect.

Tonics—wine and iron—should follow above treatment. Should diarrhœa follow severely, give opiates in suitable doses.

Natchitoches, La. W. B. POWELL, M.D.

NEWS AND MISCELLANY.

Wisconsin Law Referring to Contagious Diseases.

An important law relating to the transportation of dead bodies and the exposure to contagious diseases has been enacted in Wisconsin. We make room for its two most important clauses. The complete Act can be obtained through the Wisconsin State Board of Health:—

SECTION 1. Any person who shall bring, knowingly aid in bringing, or cause to be brought, by railroad, steamboat, sailing vessel, stage coach, or other public or private conveyance, into any town, village or city of the State of Wisconsin, the dead body of a deceased person, unless such dead body is accompanied by the written or printed certificate of a physician or coroner, clearly stating the cause of death, and unless, when the cause of death is smallpox, diphtheria, scarlet fever or other dangerous, contagious, infectious or pestilential disease, such dead body is also accompanied by the written or printed permit of a lawfully constituted public health authority, and by the sworn declaration of an undertaker, in writing, that the body of the person deceased as aforesaid is hermetically inclosed in an air tight metallic coffin, or is encased with an abundance of powerful disinfectants according to the written or printed directions of said public health authority, so as to render the same entirely innocuous, shall be deemed guilty of a misdemeanor, and on conviction thereof, shall be punished by a fine of not less than fifty dollars, nor more than three hundred dollars, or by imprisonment in the county jail not less than twenty days, nor more than three hundred days.

SECTION 4. Any person knowingly laboring under smallpox, diphtheria, scarlet fever, or other dangerous, contagious, infectious or pestilential disease, who shall willfully enter a public place or a public conveyance, or shall in any way willfully subject others to danger of contracting his disease, or any person who shall knowingly and willfully take, aid in taking, or cause to be taken, a child or other irresponsible person while laboring under any of the aforesaid diseases into a public place or public conveyance, or shall in any way knowingly and willfully sub-

ject others to danger of contracting any of the aforesaid diseases from such child or irresponsible person, or any person who shall knowingly and willfully subject others to danger of contracting any of the aforesaid diseases from the dead body of a person deceased thereof, or any person who shall in any way, knowingly and willfully expose, aid in exposing, or cause to be exposed a child or other irresponsible person to danger of contracting any of the aforesaid diseases, shall be deemed guilty of a misdemeanor, and shall be subject to the same penalties as are provided in section one of this Act.

Professional Profits.

The money prizes are few in our profession, go where you will. An English contemporary states that in Glasgow the examinership of an insurance company, paying about $75.00 per year, was eagerly sought by not less than thirty medical men, some holding high positions! Prof. Cameron, in his valedictory address to the graduating class at Bishop's College, Montreal, says: "Let me urge upon you not to begin practice with too great mercenary inclinations; if money-making is your aim in life, I fear you sadly missed your vocation; you should, really, gentlemen, have chosen some other calling. Undoubtedly the laborer is worthy of his hire, and people, as a rule, do appreciate kindness, attention and skill, and gratefully remunerate them as they deserve; while you need, therefore, feel no hesitation in expecting or receiving a fair equivalent for your time and labor, be not discouraged or disheartened if you do occasionally meet with inconsiderateness and ingratitude; but you should endeavor to sink, as far as possible, the money aspect of the question, and go forth into practice seeking rather how you may best be of use in the world, how you may best combat disease and alleviate pain and suffering."

This is good advice, but after all, doctors must live and support their families, as much as other people, and more practical words would have been more to the purpose.

The Sanitary Division of the Seasons.

The arbitrary division of the year into four seasons is not satisfactory for the purposes of sanitary statistics. In the recent lectures of Dr. William A. Guy, of Cambridge, England, he has proposed, at least for the climate of England, a division into three periods of four months each; the four hottest months being June, July, August, and September; the four coldest, December, January, February and March; and the four temperate, April, May, October and November. This division has one or two obvious advantages. In the first place, it creates, for comparison, two extremes and an average. In the second place it necessitates only one act of rectification, and that only needed when we are not dealing with a leap year. The temperate and the hot months consist each of 122 days, and so do the cold months in leap year. In other years, the three periods are made of equal length, by adding to the four cold months the fraction $\frac{1}{121}$.

The average temperatures of these three divisions are as follows: Four coldest months, 40.0; four temperate months, 49.4; four hottest months, 62.3; the difference between the four coldest and four temperate months being 9.4, and between the four temperate and four hottest months, 12.9, making the difference between the four coldest and four hottest months, 22.3.

By this arrangement, too, the average temperature of the four cold months (40.0°) is widely separated from that of the four hot months (62.3°).

French statistics, however, give us reason to believe that the order of the seasons, as it prevails in the more temperate climates, does not obtain in warmer countries; and it is likely that the Roman physician, Celsus, had reference to the warmer parts of Italy, when he made the well-known statement, that the healthiest season was the spring, then winter, then summer, and lastly the autumn. The figures for Marseilles and Montpellier agree in placing the Roman spring at the top of the scale, as the healthiest season, and the Roman autumn at the bottom, as the most fatal to life.

In the United States, the highest mortality in cities is in the hot months.

Plans for Insane Asylums.

Dr. Bucke, of the London, Ontario, Asylum, says, in his last report, that the plan of having separate buildings, something on the cottage plan, for violent cases, those of filthy habits, etc., has, notwithstanding the adverse opinion of experts, proved a success so far as carried out in that asylum.

Dr. Bucke says that he is firmly persuaded that a still further division of an asylum into buildings under separate roofs, than is here practiced, might be adopted with great advantage, and that many of the problems in asylum construction may be solved by the abolition of the large single building, and the use of a number of smaller buildings in its place. Some of the advantages of the latter system would be more perfect isolation of one class of patients from all other classes, and the greater facility of systematic classification of patients; greater facility for lighting the buildings; better ventilation without fans and steam power than can be had with these in a very large building, and consequently better health of the patients, a lower death rate, and less cost of construction. To construct an asylum for a thousand patients, he would have it composed of not less than ten or twelve separate buildings, the largest to contain not more than two hundred patients, and the smallest between fifty and a hundred.

Resection of the Stomach.

Prof. Billroth's remarkable employment of "heroic" surgery, on January 29th, when he excised a considerable portion of the stomach, including pylorus, in a woman suffering from cancer of that organ, was so successful that he has twice since repeated the operation. These latter cases, however, were unsatisfactory, one living but eight days after; the other only twelve hours.

The original operation was performed with the first intention of exploration simply. Two days after the operation, the patient took food by the mouth, and on the eighth day the sutures were removed from the abdominal wall. The favorable progress was not interrupted in this case, convalescence having set in, and solid food having been resorted to, without any disastrous consequences. The patient, two months after, continued well; and the success of the operation in her case apparently indicates its feasibility in that class of diseases of which hers was an example. Certainly, for novelty and boldness, it would be hard to parallel the case.

Mortality in Tenement Houses.

Speaking of the alleged increase of mortality in the New York tenement houses, Dr. C. E. Nelson says, in a letter to the *Canada Med. Record*:—

I think this is due to the fact, principally, that there are more poor people than rich; also, that there are more people occupying a room (merely as regards simple numbers) in tenements than in rich houses. Send away the bulk of the tenement house population, leaving merely as many people in a tenement house as there would be, on an average, in a rich house, it is a question whether any more would die in the former than in the latter; of course, there is a little difference as regards buying delicacies, getting good food, wines, etc. The laboring men who live in tenements go to their work every morning, perfectly healthy, although of course they are in the fresh air most of the day; the mothers pass through their confinements about as well as the rich ladies do.

Poisoning from Milk.

An illustration of the poisonous action of impure milk was lately seen at Aberdeen, Scotland. All the patients consumed the milk of one farm, the cows of which had been fed on diseased turnips. The disease was ushered in by a severe rigor, which was followed by headache, backache, high temperature, and sore throat; the tonsils being deeply injected, and the lymphatics in the neck swollen and exceedingly painful. In no case was there any false membrane on the mucous covering of the throat. In most of the cases the symptoms gradually abated, and convalescence was established on the fourth day, but in some relapses took place, and the symptoms reappeared. The disease was chiefly met with in one end of the town, and in some households seven, nine, and twelve members were affected at the same time.

Diminution in the Size of Heads.

A curious fact has been brought out in England (*British Med. Journal*, April 16th). It appears that there has been in the last thirty years a progressive diminution of the size of the heads of the people, a change noted by the hat manufacturers in all parts. They have reduced the average hats for the market at least two sizes during that time. The precise significance of this singular fact has yet to be ascertained.

The Very Earliest Instance of Anæsthesia.

The Vienna *Montags Blätter* states that in M. Edward Albert's work on the *Surgical Diseases of the Head and Neck*, of which the second edition of the first volume has just appeared, there is a passage treating upon narcotics, and containing the following anecdote: When Sir James Simpson proposed the use of chloroform in confinement cases, the religious zealots in England got up an agitation against it, on the ground of the scriptural curse, "In sorrow thou shalt bring forth children." Sir James quickly answered this party, which even comprised some doctors, with the biblical fact that God narcotized Adam (*immisit soporem*—"caused a deep sleep to fall upon him") when he created Eve out of his rib.

The Origin of Syphilis.

An English physician, practicing in Brazil, writes to the London *Medical Times and Gazette*, on this subject:—

"I am much inclined to believe that the disease known in Brazil as *Boubas* (the African yaws) is the parent of modern syphilis, and the identical disease which appeared suddenly in Europe in the sixteenth century. This disease is transmissible in a most acute degree, and sexual intercourse is by no means the usual mode of contagion. It is practically incurable, because, though the internal signs are removed, the constitution continues damaged through life. The external symptoms are not reproducible a second time, so that only those who have been once attacked can act as nurses to boubatic patients."

Curious Statistics of Color Blindness.

The latest reports to the English Ophthalmological Society, based on over 18,000 examinations, show that while the average percentage of color defects in men is 4.76, it falls in women to the low figure of 0.4. This is, no doubt, owing to the much greater training women receive in the differentiation of colors. A fact pointed out many years ago is, that color blindness is more frequent among members of the Society of Friends than other religious sects. The cause of this lies close at hand, in their avoidance of bright colors and prejudices against art in many of its brilliant forms.

Increase in Hereditary Syphilis.

From 1847 to 1853, syphilis destroyed, in England and Wales, an annual average of 565 infants under one year old in each million of births; in 1878, the deaths under this head had risen to 1851 per million. Part of this increase was probably owing to increased accuracy in diagnosis.

True Test of Vaccination.

An English physician, Dr. Robert Cory, in a letter to the London *Times*, has pointed out that the efficacy of vaccination does not rest upon statistical data alone—data of which it is not at all times easy to understand the whole meaning,

or to avoid fallacies in dealing with them—but on the result of actual experiment. The efficacy of vaccination was, in the first instance, proved by very numerous but unsuccessful attempts to inoculate the vaccinated with smallpox, so numerous as to justify the Legislature to forbid the practice of inoculation by smallpox in any case, and to first facilitate and then enforce the practice of vaccination.

The Coca Leaf.

An excellent authority, Mr. Clement Markham, has recently written a book on "Peruvian Barks," in which he also mentions the coca plant. He observed that the yield of coca in South America is estimated at thirty millions of pounds. Coca soon deteriorates in keeping, and Indians treat it as valueless if kept longer than seven months, which may explain its slight effect with us.

Such is the faith in coca, that it is believed if a dying man can but taste a coca leaf when placed on his tongue, his future bliss is assured. No Indian is without his *cuspa* or coca bag, made of llama cloth, and three times a day, sitting down, he takes leaf by leaf and rolls them up in his mouth till he forms a ball. Then applying a small quantity of powder, consisting of carbonate of potash, made by burning the stalks of the quinoa plant, mixed with lime and water, he goes on his way rejoicing.

Mr. Markham chewed coca leaf very frequently, and states that he found it to produce an agreeable, soothing feeling; that he could endure longer abstinence from food with less inconvenience, and that when using it, he could ascend precipitous mountain sides with a feeling of lightness and elasticity, and without losing breath. He also considers it the least injurious of all other like substances, even when taken in excess, and at the same time the most soothing and invig orating.

The Propagation of Syphilis by Razors.

M. Desprès has lately published two cases in which syphilis appeared to have been communicated through the medium of the razor during the process of shaving (*Journal des Connaissances Médicales*, quoted by the *Brit. Med. Jour.*) In the first case, a man, aged fifty four, of steady habits, and with no history of venereal disease, was shaved by a barber on July 11th, 1880. The man observed, after being shaved, that he had three small cuts on the chin. On July 25th, the patient (who had had no relation with women for ten weeks) noticed a swelling at the site of each of the cuts first noticed after the shaving. On September 1st, the patient came under the care of M. Desprès, having been sent to the surgeon as a case of epithelioma. On examination, there were found three ulcers on the chin, surrounded by some red and moderately hard callosities. There was a hard gland beneath the jaw, but none elsewhere. No other signs of syphilis were discovered at that time. On September 15th, a papular syphilide appeared. The second case, that of a young man, aged twenty-two, was in many respects similar to the preceding; in him, also, the initial lesion appeared on the chin, but the patient did not remember having been cut by the razor. In due time, glandular enlargement and a general syphilide followed.

Poisoning from Aconite.

A fluid drachm of tincture of aconite is a startling dose for a child to take and recover from. Yet such a case was related recently at the Toronto Medical Society, by Dr. Carroll. Of course, it was through inadvertence. Thirty minims of tr. aconite were given at 7 A.M., and no symptoms appeared until a second dose at 10 was given, when vomiting, accompanied by alarming symptoms of prostration, set in. Large doses of ammonia were given and the child recovered. Possibly the tincture was weaker than the standard.

Curious Cosmetic Invention.

In Paris, says the *Lancet*, false ears are a new manufacture for the toilet. Ladies who think they have ugly ears place these artistic productions under luxuriant tresses of false hair, fasten them to the natural ears, and wear them for show. False hair, false teeth, false breasts, false hips, false calves, false ears—what next?

Iowa State Medical Society.

The Twenty-ninth Annual session of the Iowa State Medical Society was held in Dubuque, beginning Wednesday, May 25th, 1881, at 10 A.M. A large attendance was present, and it was an interesting session.

J. F. Kennedy, *Sec'y.*

Personal.

—Sir William Jenner, M.D., has been elected President of the Royal College of Physicians of London.

—A "great American rheumatic doctor" has been sent to jail in Bristol, England, for practicing medicine without a license.

—Prof. Helmholtz has been making a visit to Great Britain this spring, and has been received with distinguished honors by the medical societies.

—Dr. John Day, of Australia, well known for his researches on ozone, the peroxide of hydrogen, and other disinfectants, died in January last.

—Prof. Waldenburg, editor of one of the most esteemed German medical journals, the *Berliner Klinische Wochenschrift*, died last month, in Berlin.

—In his recent visit to Russia, Professor Charcot was entertained by Madame Dr. Tarnovsky, a woman practitioner of eminence in St. Petersburg. The Professor, at a professional banquet, expressed himself in terms of high praise about the "lady doctors," setting an example to the profession across the channel which they ought to imitate.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O	
Quinidia do	15 "	20	24	2	2	
Cinchonidia do	15 "	C	H	N	O	
Cinchonia do	15 "	20	24	2		
Chinoidine Purified,	30 "					

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

A CHRONIC AFFECTION OF THE LIVER AND STOMACH OF HABITUAL DRINKERS OF STRONG ALCOHOLIC LIQUORS. THE SYMPTOMS AND TREATMENT OF THE COMPLAINT.

BY HUGO ENGEL, A.M., M.D., F.A.A.M,
Of Philadelphia.

Persons who imbibe a liberal quantity of strong alcoholic liquor daily, perhaps without ever reaching that degree of intoxication in which they could be considered really drunk, are affected sooner or later by a train of symptoms which are so peculiar, and at the same time—taken as a group—so pathognomonic, that in the individual complaining of them, the tippler, the stage he has reached, his exact pathological condition, and the cause of it, become at once apparent, as only such persons can be affected in the manner soon to be described, who have habitually been drinking such strong alcoholic liquors as cognac, brandy, whisky, rum, arrack, gin, kuemmel, bitters, zwetschenwasser, and other stimulants of the same class. I have never seen a wine, beer, porter or ale drinker with any of these symptoms; but in those who drink, besides the last-named beverages (wine, beer, porter, ale, etc.), between, or mixed with these, the stronger alcoholic liquors first enumerated by me, "to settle their stomach," as they say, I have found these symptoms the most stubborn. And here allow me to make a few more remarks concerning the different kinds of tipplers. There are many persons, especially Germans, who will drink only wine * or beer, and never any other intoxicating liquid, under any circumstances, except, perhaps, when ill and ordered to do so by their physician. These persons are free from the symptoms in question, and there would be a far greater number of them if many wine or beer drinkers did not regularly imbibe, besides their usual main beverage, a little whisky, "now and then," or one of the three following liquors, which they consider harmless, but which are just the cause of the symptoms mentioned, even if producing the latter after a much longer period, because taken in smaller quantities, viz: bitters, zwetschenwasser, and kuemmel. The first consists, generally, of common proof-spirits, to which aloës, gentian, rhubarb, cinchona (rarely), or some other vegetable bitters have been added. The second is a very strong liquor, containing mostly 65 per cent. alcohol, and is made by the distillation of prunes or plums (kernels and all). And what makes matters worse, these two are generally taken on an empty stomach in the morning; a bad habit, the danger of which I will explain hereafter. The last of the three "innocents" consists of common proof-spirits, to which the essence of caraway seed has been added. It is mostly taken by the habitual drinkers of that least dangerous of all intoxicating beverages, weissbier (containing about 2 per cent. alcohol), to stimulate the expulsion of gases from the intestines, the weissbier being very rich in carbonic acid. Drinkers of wine or of malt liquors consider the three beverages just described harmless, but forget how many doses of them they take daily, and

* By wine, I mean the good European wines. Most of the American wines contain such a high percentage of alcohol, and so often of fusil oil, that they have to be classed with the strong alcoholic liquors.

that these potations generally contain more alcohol, and what is worse, more fusil oil, than good whisky does. Then there is a class of drinkers who regularly refresh themselves daily with an unlimited number of drinks of the strong alcoholic liquors, which they take undiluted. Such persons are, perhaps, never drunk, but not far from that point, and never totally sober. The two classes just mentioned are the tipplers mostly concerning us here; those, therefore, who really consider themselves only wine or beer drinkers, and apparently abhor whisky, but in facto imbibe with their zwetschenwasser, bitters and kuemmel almost the same quantity of alcohol and perhaps more fusil oil, than the other class, who drink whisky, brandy, etc., therefore, the stronger alcoholic beverages, habitually. The only difference, from our standpoint of view, between the two consists in the fact that the first class enjoys a longer immunity from the symptoms soon to be described than the second class, which has to suffer earlier. Persons who drink only wine or beer are exempt from these symptoms, while individuals who often get actually drunk, or those who are strictly temperate for a certain time and then suddenly go on a longer or shorter "spree," become differently affected, both the latter being threatened by delirium tremens, and more serious organic lesions than the first two classes described. Here we have only to do with the regular tippler, who, whatever else he may drink, imbibes daily a certain quantity of strong alcoholic liquor, without ever, perhaps, getting actually drunk.

Before describing the symptoms, I will mention one important fact as regards alcoholic liquors. In certain parts of the Prussian provinces of "Pommern" and "Westphalen" these strong drinks are habitually used by the inhabitants. Why is it that the latter are comparatively free from these symptoms, from which the drinkers of the same liquors in other countries have to suffer so much? One cause evidently lies in the fact that a "Pommer" or a "Westphale" will rarely use any liquor except he, at the same time, fills his stomach with a heavy meal, of which the so very nourishing rye bread of those localities forms no small part. Another and, perhaps, just as weighty a reason, is that the people generally prepare the liquor themselves, from rye, prunes, or other fruit, and that these beverages are remarkably free from fusil oil, amyl. On the other hand, to find any of the common strong alcoholic liquors of this country free from fusil oil, is a rare exception.

The very first intimation of the tippler having reached that stage where he cannot well do without his habitual dose of alcohol, in some form or other, is a symptom which generally precedes for a long time those now about to be mentioned: it is a craving for a drink early in the morning, before any food has been taken, consequently, on an empty stomach. This early stimulant, taken in the beginning, simply because there is a desire for it, soon becomes a necessity in order to "steady" the nerves, and, further still, to "settle" the stomach. This drinking on the empty stomach is the most dangerous habit such men can adopt; it does more harm than all the other drinks of the day taken together, and all habitual tipplers crave for that one drink more than anything else. If such persons could be aware of the fact that in the morning, before the first meal, the absorbing vessels may be compared to dried sponges, which readily absorb any moisture they come in contact with, then they would know that these "morning drams" are absorbed in an almost unaltered state,* and, therefore, cause the greatest damage to the stomach, and, being carried along the portal system, to the liver. This direct introduction of the alcohol into the circulation is the cause of the nerves of the habitual drinker becoming so quickly "steadied" after this first drink in the morning, just as the direct stimulation of the ramifications of the pneumogastric and vasomotor nerves causes the "settling" of the stomach. I have observed inveterate tipplers endeavoring, with shaking hands, to carry the first morning drink to their lips; have seen them verify the old adage, "There is many a slip between the cup and the lip;" and a minute or two later have been astonished to see these same once trembling persons delicately hold the second glass between their fingers and take the second drink with hands as steady as though it was the first liquor that had ever passed their lips. But this magical effect is just the reason that no warning will ever prevent them from gradually undermining their constitution more and more.

The early morning drink once having become an established habit, the other symptoms soon make their appearance. The patient suffers from nausea in the morning, loses his appetite for breakfast especially, and complains of occasional sour eructation, and more frequently returning

* Besides, the stomachs of tipplers are coated in the morning with tenacious mucus, etc., which prevents the action of the gastric juice, favored by the temperature of the stomach, on the alcohol, and the decomposition of the latter into its composing elements ($C_4 H_6 O_2$) while a cup of hot coffee will remove the accumulated mucus, and alcohol may act as a nourishment. The least dangerous consequences follow, therefore, when the liquor is taken on a full stomach.

heartburn. Soon another symptom is added. The patient has a feeling of weight in the epigastrium after each meal; and the stomach becomes sensitive to the touch. The nausea soon changes to vomiting, and regularly every morning large quantities of glairy mucus, which have an extremely sour taste and smell, are ejected by the stomach. Frequent belching takes place, which is always connected with a sour taste; the appetite becomes more and more irregular; the bowels incline to constipation, alternating sometimes with diarrhœa; the feeling of weight and distention increases in severity, as also the sensibility of the stomach to pressure and touch. And the feeling of weight is not only there after eating, and is not confined to the epigastric region alone; there is now a constant sensation of fullness in the right hypochondrium; pain is experienced there more or less constantly, and a physical examination reveals an increased area of liver dullness. Besides these symptoms there are inward fever, great thirst, headache, and all kinds of neuralgic pains. Hemorrhoids generally make their appearance; the sleep is restless, disturbed by dreams; the muscles tremble in the morning; the face looks tumid, and the tongue is coated, indented by the teeth and red at the tip.

These symptoms form, as a whole, a picture which is so frequently seen, and with few alterations—due to peculiarities of the person—it is always the same, that it is easily recognized. The appearance of face, skin and tongue, the peculiar vomiting in the morning, the other dyspeptic symptoms in connection with the subjective sensations in the epigastrium and right hypochondrium, the sensitiveness of the stomach to touch; no other disease presents the same group of symptoms and signs. And no matter what else may ail the patient, no matter what organic disease may cause other phenomena of its own besides the symptoms mentioned, the latter always stand preëminently in the foreground and form a group for themselves.

But now, we ask ourselves, what is the pathological condition that produces this state, this train of symptoms? Chronic gastritis and a peculiar chronic inflammation of the liver.* We do not often see the morbid process at this stage, as death takes place after more serious organic changes have occurred; either the inflammation of the liver makes rapid progress and cirrhosis sets in, or delirium tremens, or affections of the heart, brain, lungs, or kidneys, end life later. In the liver we find Glisson's capsule in the state of chronic inflammation; the tissue is swollen and presses upon the fine ramifications of the portal vein, causing thereby congestion of the abdominal viscera, especially the stomach. It is in this stage that, by relieving the portal circulation, and taking, as it were, the nutrition away from the inflammation, the latter rapidly recedes and the inflammatory products become absorbed. If, on the other hand, contraction of the fibrous tissue has begun, no remedy can prevent the further and now rapid progress of that fatal malady, cirrhosis of the liver.

When there is no pain on pressure, and nothing abnormal left in the right hypochondriac region, except a sensation of fullness, then we have only to do with congestion of the liver, and the symptoms regarding the latter are milder. The stomach shows the well known appearance of chronic inflammation, for a detailed description of which I must refer the reader to any of the many works on special pathology.

I shall now describe the treatment. If the patient has no other organic malady, and follows the directions of the physician exactly, in every detail, from one to two weeks will be sufficient time during which to remove nearly every one of the symptoms or lessen the degree of severity of them so much as to bring the patient out of his miserable condition, as it were, by a miracle almost. In no case, *cæteris paribus*, have I found any exception to this rule. The treatment is as follows:—

The patient must immediately omit all intoxicating drinks; not the smallest quantity is to be allowed to him. Many contend that the liquor should be gradually withdrawn, or dangerous symptoms may arise. This is theory; experience gives a different result.

"Grau, Freund, ist alle Theorie,
Doch grün des Lebens bunter Baum."*

The liquor must absolutely be dispensed with from the very beginning; the patient must not permit a drop to pass his lips under any circumstances, from the moment the treatment commences. The physician must use all his energy and power of persuasion to gain this point; he must convince the patient of the absolute necessity of this, and of the danger threatening the

* "The liver of drinkers frequently undergoes a series of pathological metamorphoses, which begin with the formation of the nutmeg liver and lead through the fatty liver to cirrhosis of the same. In connection herewith we observe, rarer, though, than post-mortem examinations should warrant us to expect, all kinds of phenomena of chronic affection of the liver; symptoms which undoubtedly are under the influence of the alcoholic blood of the portal vein." (Falck, in Virchow's Handbuch der Pathologie and Therapie, Vol. II, p. 1. page 302; Erlangen, 1855.)

* Goethe, translated:—
Gray, Friend, is every Theory,
But green is ever life's gay tree.

tippler should he no strictly follow the advice given. A physician who does not insist on this sudden and total stoppage of the usual stimulant, will never effect a cure. The few symptoms which may be caused by this abrupt withdrawal will, together with the treatment of the same, be described below.

The patient is also directed to take but three meals daily; say, for instance, at 7 A.M., 1.30, and 6.30 P.M.; that is, at regular and definite intervals, to give the stomach the so much needed rest; these meals to consist simply of several cups of milk (unboiled, hot, warm, or cold), to which lime water is added (f.℥ ij to Oj); a few slices of dry toasted wheat-bread and butter, and once a day—at noon—one or, at the most, two soft-boiled eggs. A little barley gruel, some beef tea, bouillon, boiled rice, soups of any kind (but not fatty), or chocolate may occasionally take the place of the milk; and here and there, to interrupt the monotony of this bland diet, a mealy, mashed potato, or a little celery or radish, may be permitted. But any other diet must be strictly avoided; even the articles mentioned as substitutes, or to change the taste slightly, should only be used when there seems an imperative demand for it. Some people insist that the milk makes them bilious, a fact or assertion of the truth of which I have had no proof where the milk was used according to directions. A whole cup of milk should not be emptied into the stomach at once, but the milk should be swallowed gradually and some toasted bread eaten between each mouthful of milk. I do admit, however, that there are persons who have an idiosyncrasy against milk. Such individuals must take some of the substitutes, but must never omit the milk totally. Happily, such cases among drinkers form a rare exception to the general rule. Milk is generally liked very much.

The patient is advised also to take a lukewarm bath every morning, one hour and a half before breakfast, to stay only four to five minutes in the bath, and to afterwards rub himself thoroughly dry with a coarse towel. Finally, he must take daily walks out in the fresh air, for at least one hour and a half, and give himself as much physical exercise as possible without fatiguing himself, and by no means take a "nap" during daytime. He should arise in the morning and go to bed every night at the same hours, say, at 7 A.M., and and 10 P.M., respectively. This is the hygienic method of treatment; now let me describe the medical treatment.

The patient is directed to take the following the first night when going to bed:—

℞.* Mass. pilul. hydrarg. gr. vi, usque ad gr. xv.
Ext. hyoscyami gr. ij. M.
Ft. pilulæ No. ij.
SIG.—As directed.

And the morning following, six drachms of Rochelle salt in a tumblerful of water, on the empty stomach, the same to be repeated every sixth day until there is not the slightest trace of yellow coating on the tongue. The following medicine is prescribed, which the patient begins at noon of the day he takes the Rochelle salt the first time:—

℞.† Sodii bicarbon., ℥ ss
Tinct. nucis vomic., f. ℥ j
Tinct. gentian comp., f. ℥ iv. M.
Two teaspoonfuls in water, three times daily, one hour before each meal. Shake well.

Should the bowels continue constipated, the patient is to take one of the following pills at night, on going to bed, whenever there has been no motion during the day.

℞. Podophyllin, gr. vj
Pulv. aloës soc., gr. xxiv
Ext. hyoscyami, gr. xlviij
Glycerin,
Gm. acaciæ, āā q.s., ut ft. pil. No. xxiv.
SIG.—As directed.

Externally the patient has to apply (after having, in case of much hair growing in the epigastric region, shaved off the same) the following fly blister, covering with it the whole stomach, and—laying it a little to the right—a part of the right lobe of the liver also:—

℞. Emplastr. cantharid., 6½″–8½″
Consperge cum., morph. acet., gr. iss.
Ft. emplastrum.
SIG.—Externally.

After eight hours the plaster is to be cautiously removed—a procedure which, on account of the severe burning pain that invariably occurs whenever the epidermis is destroyed, must be delicately performed, so as not to tear the latter off—then a hot poultice is to be applied for an hour or less.‡ after which the blister or blisters that

* The dose of the blue pill depends, as a practical rule, upon the corpulence of the patient; the fatter he is the larger the dose. The henbane is added to prevent griping, which in some persons is rather severe when taking blue mass. I may add, that it is better not to let the patient know what he is taking, because some have superstitious objection to blue pill, while others, again, would repeat the dose too frequently of their own accord, and by omitting the Rochelle salt, which they are generally very apt to do, injure themselves.

† Originally and frequently prescribed by Prof. Da Costa in his clinics, while I was acting chief of the latter. Some enterprising firm in the West made a patent medicine out of it, and called it—to the no slight chagrin of the Professor—Da Costa's cure for dyspepsia. When indicated, its effect is remarkable.

‡ If the blisters have all formed on removal of the plaster, the poultice can be omitted. The latter favors the development of blisters decidedly. I have seen

may have formed are to be opened with scissors at their most dependent point, whereupon the sore is to be dressed three times daily; as long as moisture is present, later only twice daily, with the following ointment, which is spread for this purpose upon a piece of old linen, patent lint, prepared cotton, or, still better, linen charpie:—

℞. Unguent. zinci benz., ℥ iiss
Acid. carbolic., gr. v
Bals. Peruvian., f. ℥ iiiss.
Tere quam subtilissime, ut fiat unguent.

Sig.—Externally.

After a period varying from about six to twelve days the patient will be relieved of every symptom he had, except some slight feeling of weight in the epigastric region after eating. If this is the case, and all vomiting, sour eructations, nausea, etc., have ceased, he is given, in addition:—

℞. Liquor pepsinæ, f. ℥ vss
Acid. muriat. dilut., f. ℥ ss. M.

Sig.—Two teaspoonfuls in a tumblerful of water, three times daily, immediately before eating.

As soon as the patient has been free, for a week, from each and every symptom he complained of, he is gradually brought back to his usual diet, and if he then continues in the same good condition for a week, the sodium mixture is first omitted. and everything progressing favorably for a week or more, the pepsin also. It is safer not to drop any of the remedies suddenly, but to do so by gradually lessening the dose. If the same cause does not, *de novo*, reproduce the symptoms, the latter, having once fully disappeared (notwithstanding the patient is taking his usual nourishment and no medicine), will never reappear. Whenever, while the patient is still under treatment, any of the symptoms return, the treatment just dropped has to be taken up again; I mean by this, not the whole treatment, but only that part of it which had just before been omitted.

By following this treatment to the very letter, omitting nothing whatever of it. any physician can soon convince himself of the remarkable effect of it. But there are a few symptoms. as yet, which may have to be removed by special treatment.

If about eight days after the application of the blister there is still any pain left in the epigastric or right hypochondriac regions, from six to ten European leeches must be applied to the painful place. The bleeding of the leech bites must be allowed to stop of itself. Should the pain again return—which is very rarely indeed the case—about four leeches will suffice to remove it. The number of leeches depend upon the severity of the pain and the plethoric or anæmic condition of the patient.

We now come to two symptoms which must be ascribed to the sudden withdrawal of the stimulant. They are. great nervousness, restlessness, trembling, etc., and sleepless nights. If these symptoms are not too severe and not too annoying to the patient, I allow nature to take its own way; within one or at the most two weeks the irritability of the nervous system will have ceased and sound sleep set in. A certain amount of physical exercise, as mentioned above, is here especially of value. But in case we are forced by one or the other reason to assist nature, then I know of no better treatment than the following. I will add here, that neither the slightest stimulation nor the use of opium or its preparations are *ever* indicated. I give my patients

℞. Sodii bromid., ℥ iijss
Lith. bromid., ℥ ijss
Aquæ destillat., f. ℥ v
Syrupi zingib, f. ℥ j. M.

Sig.—A tablespoonful in a tumblerful of water, in the morning, on the empty stomach, and at night when retiring.*

I have found two large doses to be more efficient than three smaller ones. As soon as the desired result seems to be achieved, the bromides must be gradually withdrawn. My usual plan is to let the patient take three teaspoonfuls for two days, then if the improvement continues, for two days two teaspoonfuls, and so on. In this way I give the bromides just as long as necessity requires.

Usually, well carried out physical exercise and the administration of the bromides will fully suffice to produce a quiet sleep during the night. But sometimes the cases are more troublesome, and the patient's health threatens to become undermined by the loss of sleep. Then, but only then, I use the following, giving the apothecary the instruction to never by any means renew the medicine nor give a copy of the prescription without my written order:—

cases where for three, four and more days, nearly daily, one or two new blisters appeared. much to the annoyance of the patient, when the application of a hot poultice for an hour would have prevented such occurrence. Besides, a hot poultice diminishes the danger of strangury, more, perhaps, than the sprinkling of the plaster with morphia does.

* In the morning, should the sodium mixture have to be taken at the same time, I leave five minutes between them; if Rochelle salt, half an hour, giving the bromides first; the cathartic pill at night—if such has to be taken—does not interfere in the least: it may be swallowed at the same time with the bromides.

℞.	Chloral. hydrat.,	℥ss	
	Mucil. gm. acac.,	f. ℥iiss	
	Aquæ destill..	f. ℥iiss	
	Liquor. morph. sulph.,	f. ℥ss.*	M.

Sig.—A tablespoonful to be injected into the bowel at bedtime.

I let the patient first go to bed, when half a fluid-ounce of this mixture is slowly injected up into the bowel, by means of a syringe, which is warmed and oiled (at the point) beforehand, and which has a capacity of a little more than half an ounce. The patient is told to withstand the slight desire to go to stool which he will feel at first, but which will disappear in a minute. The light must be turned low and the patient left alone, with one word; all is done to remove irritation of his nervous system,† and within three to fifteen minutes he will generally have fallen into a quiet sleep, lasting about eight hours, out of which he awakes refreshed and without any of the usual disagreeable sensations which generally follow the effect of a hypnotic. He may awake a few times, but only to fall quickly asleep again within one or two minutes. A larger dose or a repetition of the first in the same night is, in those cases I here speak of, never necessary. After I have employed the remedy this way for three or four nights, I commence to decrease the dose one drachm‡ each following night, or in some bad cases, half a drachm, taking the greatest care to prevent the chloral habit. In cases where I have to use chloral, I give the bromides a longer time in full doses, and only begin to decrease them, after I have omitted the chloral for two nights with good results. The patient in this way feels much less the withdrawal of the latter remedy. Chloral is always best administered by the rectum, as by the mouth it easily disturbs digestion; patients dislike it and a larger dose is necessary in order to get the same rapid effect. Lastly we have, when employing the injection, no cause to fear vomiting, and, therefore, a more certain result.

I hope that some of my professional brethren who have not employed it as yet will try the above treatment. They will be astonished at its uniform success, *i.e.* if they follow it in its most minute details. I will only add, in conclusion, that in some inveterate cases, which, when cured, have invariably fallen back into their old pernicious habit again, one or the other dyspeptic symptoms will stubbornly withstand all treatment, or, if at last removed, soon reappear. In such cases—after the treatment given above has been carried out fully—the subnitrate of bismuth is the best remedy. It should be given in doses of from ten to fifteen grains and between meals, therefore, on the empty stomach. Under the conditions described I have seen great good result from it, better, at least, than from any other article of our materia medica, recommended for the same purpose.

812 N. *Fifth street, Philadelphia.*

* The morphia is here only added to allay the irritability of the bowel. Although the dose is very small (gr. $\frac{2}{3}$), it is sufficient to effect a rapid disappearance of the desire to go to stool.

† I have seen the effect of the chloral postponed for several hours by friends continuing to talk with the patient after the injection had been made.

‡ Certainly, of the mixture, a teaspoonful less, therefore.

ON THE MECHANICAL TREATMENT OF SOME OF THE DISPLACEMENTS AND DISEASES OF THE UTERUS.

Extracts from a Paper read before the Obstetrical Section of the American Medical Association, at its meeting, Richmond, Va., 1881,

BY R. BEVERLY COLE, M.D., M.R.C.S., ENG.,

Prof. of Obstetrics and Gynæcology, University of California; Fellow Obstetrical Society of London; Fellow Obstetrical Society of San Francisco, etc., etc.

Without entering into an elaborate description, giving the etiology, symptomatology, varieties, degrees or treatment in detail, of the displacements of the uterus, all of which is familiar to gynæcologists and to most general practitioners, I propose to deal with this class of derangements, at this time, simply with reference to their mechanical treatment, whether complete or auxiliary.

From time immemorable, so to speak, pessaries of great variety of forms and material have been used in the treatment of displacement of this most important organ, the uterus; but Dr. Hugh Hodge, of Philadelphia, was the first to properly appreciate the true principle of shaping and adapting the instrument to the axes of the vagina and straits of the pelvis.

Until his work, "Diseases of Women," was given to the profession, no instrument was extant that fulfilled the indications in this class of cases.

The Hodge pessary, so familiar to us all, has, however, undergone many modifications and the reasons for this are easily explained.

No gynæcologist who has enjoyed a large practice has failed to encounter cases in which the Hodge pessary, as perfect as it is, has not fallen short of meeting *every* indication; hence he has felt himself not only warranted, but called upon to so change the original shape as to enable him to adapt it to the case in hand.

In 1862, conceiving the idea that the pessary would be better retained in position by depressing its sides, so that the circular muscular fibres of the vagina would apply themselves to the centre of the instrument, and thus fix it and obviate the slipping that occurred when the original was used, I gave to the profession the results of my ideas and experience. And later on, in 1863, discovering that in certain cases, particularly if the instrument happened to be a little too long, the inferior bar had a tendency to compress the urethra and give rise to trouble in the act of micturition, I depressed this portion also, which entirely overcame the difficulty.

On visiting London, however, in 1864, and meeting my friend Dr. J. Marion Sims, and comparing notes, he assured me that he had adopted the same expedient, and I, therefore, never attempted to establish my claim to the improvement.

Before and since these modifications, as we have already said, many others have been made by different gynæcologists. Among those who have given special attention in this direction I will mention James Y. Simpson, of Edinburg, Dr. Albert H. Smith, of Philadelphia, Drs. T. G. Thomas and Montrose Pallen, of New York, each from his standpoint either taking from or adding to the original instrument of Hodge, in accordance with his peculiar views as to improvement. The former of these gentlemen was in the habit of modeling his instruments in gutta-percha, for each individual case, which plan has its advantages inasmuch as it enables the practitioner to take cognizance of the peculiarities of indications and adapt or model the instrument accordingly.

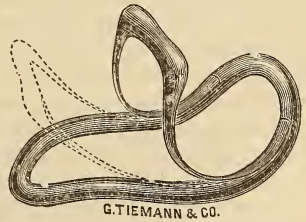
This method consists in simply softening the refined gutta-percha, by placing it, for a few minutes, in hot water, and when of a doughy consistence, rolling on a table or other smooth surface, until a proper thickness, then bringing the two ends together, so as to convert it into a ring. This done, you can give it any curve or curves required, and, while holding it in proper shape, immersing it in cold water, which immediately hardens it and gives you the instrument perfect, which we shall presently practically demonstrate.

Dr. Smith adopted the special features of both the Hodge and the Simpson pessary, producing, in some particulars, a superior instrument to either, and yet not without its faults.

But, as has occurred to each of us, cases present themselves from time to time, in which neither of the instruments extant seems to fulfill the requirements, and of these there is a class that perplexes and annoys us more than all others; it is that which is attended with great sensibility, due occasionally to a neurotic condition, but more frequently to a subacute or chronic inflammation of the parenchyma of the organ itself or the tissue surrounding it.

Under the latter condition no one doubts that we should tarry before resorting to mechanical supports, and address our remedies to the end of subduing the inflammation, and yet, when this is accomplished, for many months the tenderness is liable to continue, while the displacement contributes to its maintenance; therefore, we consider it to be of the first importance, whether the case be one of neurosis, due to retroversion, or an inflammation, subacute or chronic, due to the same or other cause, that we should replace and retain in position the displaced organ.

To meet this indication and avoid pain and irritation we have devised and used for many years the instrument here shown; it is simply Smith's pessary, shorter than usual, with the upper almost angular curve or arm so straightened as to conform merely to the curve of the floor of the vagina, while springing from the lateral bars we have two segments of watch spring, supporting at their upper extremity a bar of hard rubber, which is designed to rest in the fornix of the vagina and uterus posteriorly; in a word, the instrument is so constructed as to be of the general form of Smith's, only less angular and provided with two springs, which give it an elasticity that enables the wearer to tolerate its presence without pain or inconvenience.



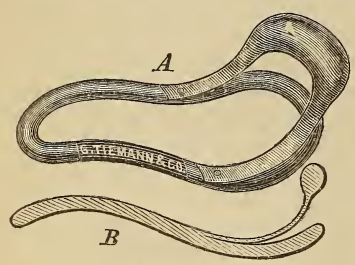
RETROVERSION.

All of us have observed that in the mechanical treatment of *acute* version and flexions, whatever be the cause or attendants, we are much more liable to encounter this extreme tenderness, or sensibility that has been described, than in *retro*-versions and flexions. This increased sensitiveness is in many instances confined to the bladder, through which the pressure, in the employment of all mechanical supports, must be exerted upon the uterus; hence any fixed support or point of pressure, such as is furnished by all acute version and flexion pessaries that have

fallen under my observation, is unbearable. And what applies to the bladder will also hold good as to the uterus itself.

Suppose that from long continued displacement irritation is set up, aided as it is by many other factors, or that from the presence of a small fibroid in the anterior wall of the uterus the organ is bent forward and its fundus carried downward; the structures are liable to become the seat of great irritability and tenderness, and the sympathy of contiguity becoming great, there is no relief except through mechanical support, so adjusted and directed as to secure the elevation of the fundus of the displaced organ from exerting pressure on the bladder, and a replacement of the uterus.

In order to accomplish this most desirable end I have devised this instrument, which in construction is similar to the retroversion, except that



ANTEVERSION.

the direction of the watch springs is reversed, and the ordinary Smith pessary is employed as the bed or support of the springs, without any modification of the superior arm or angular curve of the original instrument. I should have mentioned before that the springs in both my instruments are coated with rubber and baked, so as to render them imperishable.

After nearly twenty years' of experience in the use of this and the original instrument from which this has been taken, and which was made much more clumsily, of silver, I have no hesitation in saying that while it may not, and does not in some cases, answer the purpose, yet it is far, very far, the best I have either used or seen used.

As a law it can be well borne by the most sensitive uterus and nervous patient, giving great relief and comfort, and serving as an invaluable auxiliary in the treatment of these most troublesome and common of all the disorders of women.

The next condition of the uterus of which we shall speak is one which, though met with occasionally, either escapes detection, or is considered of too little importance to receive attention at the hands of authority. I allude to *double curvature* of the cervix uteri, consequent upon *atony* of the organ and its annexa.

As we announced at the beginning of this paper, we do not design entering into the etiology and symptomatology of these troubles, but merely to call your attention to the fact of their existence, and perhaps, in this instance, to the diagnosis, whatever the symptoms leading to physical examination be. On introducing the finger per vaginam, the os uteri will be found looking forward, the cervix elongated and resting on the posterior wall of the vagina, and so far as a diagnosis can be made through this medium, the case is one of *prolapsus* with *curvature*. When the speculum is introduced and the sound employed, the latter will be arrested in its progress at a point about one-half to three-quarters of an inch from the external os; by changing the direction of the handle, either depressing or elevating it, according to the judgment of the operator, the instrument makes another advance for the same distance, and is again arrested; changing for the third time the direction of the sound, and perhaps, reversing the position of the concavity of the instrument, it will finally pass the internal os, into the cavity of the body of the organ.

This class of cases was first described by me in the *Medical Press*, of San Francisco, in 1859 or 1860, since which we have met with this condition at least twenty or thirty times, and, as has been said, although it must have been met with by others, I have no knowledge of any written authority on the subject.

The treatment of these cases consists in triweekly introductions of the sound or stiff English elastic bougie, as large as the canal will admit, assisting its introduction by straightening the organ, either by pushing the fundus up with the index finger of the left hand—a sponge holder, depressor, or other such means, or drawing the organ down with a volsellum forceps through a Sims speculum, allowing the bougie to remain ten or fifteen minutes each time, which being a foreign body, acts as an irritant, inviting an afflux of blood to the parts, inducing active congestion, and through the distention of the vessels overcoming the curvatures, rendering patulous the cervical canal and relieving the dysmenorrhœa that always accompanies the case.

While this treatment with the sound frequently accomplishes the end in view, a much more reliable means is the "galvanic intra-uterine pessary," first introduced to the profession, so far as I know, by Prof. James Y. Simpson, of Edinburgh. This instrument consists of a staff, the upper half of which is zinc, while the lower

half is copper (one of which I here exhibit); the supposed action of this instrument is as a small "galvanic battery," inducing a feeble current, which, in its effect upon the uterus, as you can well understand, is excitant, attracting blood to the part and imparting tone to the organ; but, as is well known to all who have given study to the subject of "galvanism" and electricity, the current always takes the shortest route from the zinc plate or generator to the copp r or keeper; hence, as the staff is divided, or rather, is united in the centre at its short diameter, the current amounts to but very little.

An improvement upon this instrument I made some years ago, which I have found to render the pessary (as a battery) much more powerful and efficient; it consists, as I here show you, in

GALVANIC PESSARY.

running the plates of zinc and copper longitudi nally, separating or insulating them by the interposition of a thin sheet of hard rubber; by this arrangement we obtain action along the entire length of the staff, instead of, as in the other instrument, at one small point, and consequently it must be more effective.

This instrument is, for the most part, easily introduced, by drawing the uterus down through the Sims speculum, which straightens the canal, and when employed should, for the purpose of cleansing it, be removed at least once a week.

During the use of the galvanic pessary it is needless for me to say that a properly directed constitutional treatment, as in most uterine troubles, is indispensable.

Before leaving the consideration of this little, and, as I think, invaluable instrument, allow me to trespass upon your time briefly, while I describe another condition, in the trea ment of which I assert it has no equal, and in which, so far as my experience goes (it having been large), it never fails. This is a broad assertion to make, but I feel that my observation justifies it. I speak of *super involution*, or that condition which sometimes follows delivery at full term, in which the physiological process through which the enlarged uterus is absorbed and restored to its original and normal state is carried too far, and atrophy results.

These cases, in my experience, have been invariably attended with cachexia, and an indefinite suspension of the menstrual function. So frequently have I met with these cases, that now, when a woman consults me with the following history, namely: that she was delivered at full term of a healthy child (at a period variously remote, from one to many years), and that her recovery, or "getting up," was entirely satisfactory, and that since she has weaned her child no return of menstruation has occurred, and that she is growing weak, pale or anæmic, with cold feet and hands and a tendency to hysteria, no unusual indisposition having expressed itself during the time, I always suspect, and am usually right, that she is the subject of super involution. An examination and the employment of the sound soon determines the fact.

The treatment of these cases consists distinctly in the persistent use or employment of the "galvanic intra-uterine pessary," beginning with one of such length as will agree with the measurement of the uterus as ascertained through the sound, and gradually increasing their length as the organ develops in size, which, as has been said, *will result*, and that in from two to three months. I have in this way, after an absence of the menstrual function for five years, restored the uterus, which at first measurement was but one and a quarter inches in length, till finally at the end of three months it measured two and three-quarter inches; the menstruation returning, and in due time pregnancy supervening.

The notes of a number of such cases justify me, I repeat, in commending the galvanic pessary in their treatment.

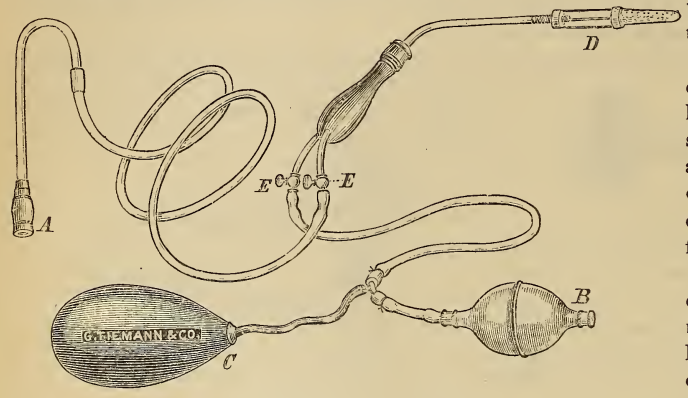
We now come to the consideration of an affection familiar to all of you, viz., menorrhagia and metrorrhagia due to granular inflammation or degeneration of the endometrium, ulcer, cancer, and fungous degeneration of the mucous lining of the uterus. Without entering into detail as to the means of diagnosis at our command, and presuming that this has been arrived at, whether it be one or other of these diseases that gives rise to the excessive hemorrhage, the indication is distinctly the same in each, viz., to remove the cause, so far as may be possible, by destroying the bleeding, diseased surface and establishing a healthy action in the tissues beneath.

To generalize, the curette, Vienna paste, chloride of zinc, and other escharotics and astringents of every kind, and finally the actual cautery, have each had their advocates, and doubtless each has been productive of good in the treatment of these cases; without descanting on their relative merits, suffice it to say that where granular or fungous degeneration, ulcer or cancer exist,

and can be brought into view, even though the sponge tent be necessary as an auxiliary aid or means, most authorities agree that the actual cautery is invaluable, and perhaps the most reliable agent in the treatment of these diseases.

When this is the conclusion of the practitioner, the question arises, how best to employ it?

We have the ordinary brutal instrument, the *iron*, heated by means of the flame or fire, and blow-pipe, which generally cools before it can be applied. We have the thermo-cautery of Paquelin, of Paris, which, although a good instrument when it works, *never works when wanted.* We have the gas jet, which has been recommended by Thomas and others; but this requires a double speculum, between the walls of which a stream of cold water is kept running, at great inconvenience to all parties. And we have what I now introduce to you, an instrument which is easy of manipulation and *never fails to work.*



AN IMPROVED CAUTERY.

The principle involved in its construction is not new, but the application of it in these treatments and the improvements I have made *are new*, and I am prepared to say that, under every circumstance, so long as you can command a supply of ordinary illuminating gas it will work to the entire satisfaction of the operator.

It consists of a goose neck, A, which is to be applied to an ordinary gas fixture. Through a rubber tube, connected at one extremity to this goose neck, and at the other to a metal tube at the handle, E, the gas is conveyed to the instrument. To another metal tube, at the handle, E, we have another rubber tube, which conveys the atmospheric air from the reservoir, C, the reservoir having been previously filled by the bulb-pump, B. The two metallic tubes, EE, at the handle, are furnished with stop-cocks, so as to give the operator complete command of the supply of both air and gas, thus enabling him to regulate the proportion of each in such manner as will secure perfect combustion. These metallic tubes traverse the handle, and are merged into one, so that when the flame reaches the cautery point, D, you have the highest degree of heat obtainable. Thirty seconds of time is all that will be required to produce a beautiful red heat, which experience teaches is the most desirable, since with a white heat we are liable to have hemorrhage.

The handle, it will be observed, is so bent as not to admit of the hand coming into the field of vision. Should the air bag become exhausted it may be refilled easily by employing the bulb-pump, without interrupting the operation.

In the employment of this cautery any ordinary speculum may be used, or the speculum of Sims, which enables you to bring the uterus down, thus straightening the canal, avoiding danger, and facilitating its application.

The after treatment of all cases in which the cautery may be employed, whether local or constitutional, will, of course, receive the attention of the attendant.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

CLINICAL LECTURE, BY PROF. D. HAYES AGNEW, M D., MAY 7, 1881.

(REPORTED BY GUY HINSDALE, M.D.)

Case 1.—Severe Injury of the Head, Followed by Removal of a Large Sequestrum.

This lad was admitted a week ago, presenting two fistulous openings in the scalp: one to the left and slightly below the median suture, the other on the same side, shorter and just above the temporal ridge. The abscess discharged through the fistulous opening for several months. The boy had fallen from a row of bannisters, striking his head and remaining insensible for a number of days. This insensibility was followed by paralysis, a paralysis of the right side. He has now, you see, nearly recovered, and is able to go about.

The pus collected between the scalp and the bone. Upon introducing a probe, the skull was found denuded. Dr. Harte made an incision and removed this circular piece of bone, which, you see, is about two inches and a half in diameter.

Now, what happened to produce insensibility when this lad was struck? Several things happened. There was a terrific shaking, a jar or con-

cussion of this part of the brain. In an hour, or even in ten minutes, a man may entirely recover. The man staggers, perhaps falls, and for a few moments is bewildered and confused; his head aches, and possibly he is sick at the stomach; but the patient recovers, and is soon able to go about as usual. This is a jar or shaking of the neurine, but just what constitutes such an accident it is difficult to say. The structure is disturbed, but in a short time the stunned man recovers perfectly. No critical method that we have for investigating tissue structure can detect the slightest alteration. I illustrate it by a magnet which has lost a portion of its magnetism, owing to a change of molecular arrangement.

This lad's unconscious condition continued several days. The blood vessels of the cranium and brain were paralyzed. The lumen or calibre of the vessels depend, as you know, on a central regulation by the nerves. Their power may be temporarily suspended by the force of concussion; the muscular power of their walls is lost and the blood rushes in. A large effusion of serum now takes place, and symptoms of compression are produced. The patient cannot be roused or waked up; there is complete unconsciousness. The effusion may be gradually absorbed as the nerves are restored, the symptoms abate, and, in the course of a few weeks, the patient perfectly recovers.

In this boy compression was well marked; he was oblivious to all impressions. Paralysis upon one side was complete. This may be from a variety of causes, as from an effusion of blood, and in this instance such was the case. Where did the blood come from? Probably, in this patient, from a rupture of the blood vessels in the separation of the dura mater from this piece of skull to which it was attached. If you will look at a dura mater freshly exposed you will find it dotted over with minute apertures, the openings of blood vessels. You can also see the prolongations of fibrous material which hold the dura mater in contact with the skull. There are, then, two connections, vascular and fibrous. The force is transmitted through the skull and detachment of the dura mater ensues. As the blood exudes, drop by drop, between the dura mater and the skull, this internal periosteum is still further separated and there is produced, in a very short time, well-marked symptoms of compression.

This boy was paralyzed for three days, and this occurred on the opposite side, viz., the right. We can, from the paralysis, usually predicate the place of lesion, although there are a few exceptions; nevertheless the general rule holds true.

What follows? The force which crushed the scalp has deprived the bone of its periosteum. It detached the dura mater, and the bone is therefore separated from its membranes upon both sides. Consequently, what happens? Death of the bone. It does not follow that, when on one side or the other the periosteum is detached, the bone dies, but when they both are detached it is certain to die. The bone, however, may die if only the dura mater is separated.

The effusion was absorbed; the boy has recovered his power and is comparatively well. Turn off the scalp and see the surface exposed and the work of repair going on. How does the wound fill up? By granulations. From what! From the dura mater. The surface is white or opaque, and the blood-vessels can be seen. The cicatrix will gradually contract and leave a depression upon the surface of the skull. These cicatrices sometimes have earthy matter but never actual bone. The fibrous tissue resulting serves to protect the brain beneath. That the brain can resist changes of this kind shows the great value of its investing tissues.

Case 2.—Compound Fracture of Radius and Ulna.

This patient has just been admitted. He says that he works in a factory and that his arm became entangled in the belting of the machinery. These are often terrific wounds; sometimes the arm is vulsed from the body. I have seen the entire arm torn off at the axilla.

There is an external wound here. As I lift the arm you see it falls over to the ulnar side. Both bones are broken. I feel for the ulnar artery and the radial, to see if they are injured. The radial artery beats and the other also. What is the treatment? Readjust the fragments, close the wound, and convert the case into a simple fracture. The difference between the conditions in compound and simple fracture is just the same as the difference between that in an open ulcer and in a subcutaneous section of tendon. When there is much laceration of the muscular tissue and skin, it is impossible, sometimes, to close up the wound. Here, we will draw up the parts and try to convert it into a simple fracture. Watch and see that the pus does not burrow between the muscles. I often recommend a simple dressing of white of egg, or compound tr. benzoin. It forms a crust over the wound and excludes the air. Splints for the anterior and posterior aspects of the arm, using no pressure. Cut an opening where the splint overlies the wound, and pack well with lint and oakum. We use two splints. If we flex the forearm when the anterior splint is put on, you see it cannot strike the arm in any respect. Then the upper and lower ends are padded, to prevent excoriation Placing the hand between pronation and supination, we adjust a sling and place the arm across the chest. Watch to see that there is no excoriation. Probably, to-morrow, the swelling will be very much greater than to day. If we fail to close up the gap the wound can close only by granulation tissue, a much slower process.

Case 3.—Urethral Caruncle.

Here is an interesting case. Although I have been connected with this hospital for twenty years, I have never seen a case like the one I show you to-day. This man, before his entrance to the house, had been having a bougie introduced into his urethra. He had been treated for stricture, and eight days ago this stricture had been divided by the knife. Since that time he has had severe hemorrhage. You see how pale he is. Before the operation, he says he could pass a stream as large as a goose quill. We hear a good deal, nowadays, about strictures the natural size of the urethra, through which Nos. 28 and 30 bougies can pass, but in my opinion these can be discerned only by the eye of faith!

'Tis possible there was a stricture; possibly it was this very thing that was cut that gave the free bleeding. When the loss of blood is serious, introduce a catheter and make compression over that; but in this case that was not sufficient. Dr. Harte slit up the urethra, upon its dorsal aspect, and found, half an inch from the meatus, a large caruncle. This may have produced narrowing of the tube. The caruncle was cauterized, the wound was closed by two pins, and the parts held in apposition by figure of eight sutures. That settled the question of hemorrhage.

It is highly probable that unless something had been done the man would have bled to death.

This case was new to me. I have seen small vascular growths at the meatus urinarius, but this was at one-half the depth of the glans penis. These polypoid tumors of the urethra are said to be due, occasionally, to leucorrhœa and gonorrhœa, but they commonly arise irrespective of such disease. They consist of hypertrophied papillæ, being composed of a spongy, erectile tissue, are freely supplied with nerves, very vascular, and, as was true in the case before us, often bleed freely when injured. They are of slow growth and seldom exceed a small raspberry in size.

Caruncles are far more rare in men than in women, and it is astonishing what a vast amount of suffering they sometimes give rise to. Patients will commonly complain of pain during micturition and at coition. Women of the most cheerful disposition will, in the graver cases, grow peevish, despondent and morose, and are the victims of the greatest mental and bodily distress.

What can be done to remove them? When they are attached by a pedicle, a snip of the scissors is all that is required. It may be necessary, in some cases, to dilate the canal in order to reach the growth. Where there is no pedicle, cauterization is the best treatment, and, as in the present instance, where dilatation is not admissible, you will have to expose them with the knife.

It is not possible for any man to say that he has seen everything that is likely to occur in surgery. Come into my wards and I will show you a little lad who has emphysema of the scrotum, and emphysema up to his axilla. We often see emphysema of the side, but I never saw emphysema of the scrotum. He has a broken rib. The lung is injured; air has escaped through the opening, and has pervaded the cellular tissue low enough to fill the scrotum.

Case 4.—Ulcer on the Leg.

It is proper that you know the result of operations done in this hospital. I show you to-day the man on whom the operation for strangulated hernia was done a few weeks ago. He has recovered from his strangulation and from his operation.

This same patient has two ulcers on the leg; one quite extensive and the other not so large. In the dispensary, where so many cases are treated, it is the commonest affection we have to deal with, and by far the most frequent seat is upon the leg. Their occurrence here is due to several causes. This is the lowest portion of the body and the most exposed to injury. Over the subcutaneous surface of the tibia there is very little cellulo-adipose tissue, and bruises here are apt to be followed by trouble. Then the veins are acting under great natural disadvantages. If their valves give way we have the whole column of blood pressing upon these walls. But in this case the ulcer does not depend on these causes. This patient has had a compound, comminuted fracture of the leg. I would caution you to be lenient toward your fellow practitioners in cases where there is deformity after fracture. In many cases there is necessarily deformity, and that, too, very considerable.

The ulcer depends on one of two causes, upon necrosis of a fragment, or upon displacement, where the skin is stretched and attenuated and breaks down. We have here both causes. The fragment is very near to the surface. It is possible that the ulcer is partly due to that. Then, you see, the probe goes deep into the soft, spongy tissue of the bone. The ulcers are due to the presence of diseased bone.

What is to be done? They will never heal up till the bone comes away, just as no ulcer will cicatrize in the presence of a foreign body. Caries may involve a considerable portion of this bone. We will let him alone till the fragment is detached and the ulcer is healed. It may be many months before this is accomplished. Protect the part from damage by a soft dressing. This ulcer is being treated with carbolized oil.

There is no use whatever in strapping an ulcer of this kind, but we will wait for the carious bone to be discharged.

Case 5.—Oblique Inguinal Hernia.

This patient has a very marked swelling in the left scrotum. I find it soft and baggy. When I put my finger upon it, as he coughs, I find that there is a distinct impulse communicated to the hand as though something were shot into it. The patient says that he has had the swelling six years, but that "it won't go up this time." I place my thumb on one side and fingers on the other, and, with the other hand grasping the body of the tumor, I draw it slightly downward and outward, and then, by making a gradual but firm compression of the mass, with a gurgling noise it slips back. This is, then, a reducible hernia. The patient says he has slight nausea and vomiting. Men who have hernia occasionally complain of this.

It is an oblique inguinal hernia. A proper truss should cause no excoriation, as this has done. All that is necessary is that the pad should compress the canal. Nothing can pass out when I make pressure here. All this man needs is a judiciously applied truss.

—Miss Jennie Brown, the fearless nurse, who devoted herself to the care of the sick while the yellow fever was raging at Grenada, Memphis and New Orleans, has just come into possession of a fortune by the death of her father, an eccentric old man, who hoarded his gold, and refused to live in any kind of habitation but an old canal boat.

Medical Societies.

THIRD ANNUAL CONGRESS OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

Held in the Hall of the College of Physicians, Philadelphia, May 9th, 10th, and 11th.

REPORTED FOR THE MEDICAL AND SURGICAL REPORTER.

The meeting was opened by the President, Dr. J. Solis Cohen, Monday, May 9th, at 10 A.M. After the roll call, Dr. Harrison Allen, the Chairman of the Local Committee, read an address of welcome, which was followed by the president's address. In it, Dr. Cohen called attention to the progress made in laryngology, and especially in the literature of this specialty, during the past year. He stated that there was now published a journal exclusively devoted to laryngology in America, and one in France, and that in the near future, one in Germany and one in England could be expected to appear. He also congratulated the Association on the large amount of original work done by its members during the past year. Attention was then called to the methods of illuminating the larynx by means of electricity, which had been introduced during the year; to the method of reducing the sensitiveness of the fauces by means of the ether spray; to the treatment of nasal diseases with cinchonidia and salycilate of quinia in powder; to the treatment of follicular pharyngitis and hypertrophy of the tonsils by galvano-cautery, and other novelties in laryngology, and then read an obituary notice and biographical sketch of Dr. Davis, of Chicago, the founder of the Association and its first Vice-President.

Dr. F. I. Knight, of Boston, then read a paper on lupus laryngis, in which he reported three cases of the disease, one in which the laryngeal lupus followed lupus of the face, one in which the order of sequence was reversed, and one in which no external manifestations of the disease were noticed, making this case rather doubtful. The doctor gave a minute account of the clinical features of these cases, and showed colored drawings of the laryngeal images.

Dr. Morris J. Asche, of New York, then read a paper on "Lupus of the Pharynx and Larynx," in which he first gave a report of a case of lupus of the pharynx without external lesions, and then gave a very clear résumé of what has been written on the subject. He stated that the disease was not as rare as was generally supposed, and that this supposition might be explained by the fact that different authors use different names for the affection. He further stated that the disease was more frequent in females than in males, and that lupous ulcerations usually made their appearance first in the velum palati, which fact was important in the differential diagnosis between this affection and syphilis. The prognosis, the Doctor said, was always unfavorable, and the treatment should be supportive, and locally, solid nitrate of silver and other astringents should be used, with a view to heal the ulcerations.

Both papers were discussed together, and in the discussion Dr. Lefferts, of New York, said that the differential diagnosis between lupus and syphilis of the larynx and pharynx was extremely difficult, and that he would regard every case in which there were no external evidences of the disease as doubtful, and would be inclined to regard the ulcerations as of syphilitic nature.

Dr. Andrew H. Smith, of New York, then read a paper on "Certain Neuroses of the Throat." The first of these was neuralgia, manifested in an aching pain of a remittent character, and which may or may not be associated with venous congestion of the mucous membrane. The neurotic character, he said, was apt to be overlooked in these cases, and a great deal of local treatment uselessly applied, while it should be treated as neuralgia.

The second class of neuroses comprises those cases in which the patients complain of various forms of deceptive sensations in the throat, such as a feeling of constriction or of a pressing backward of the larynx, or a feeling as of a strong pulling in one direction or another, and so forth. These sensations, the Doctor said, might possibly be explained as paresis of certain muscles, leaving others without sufficient antagonism. The third class comprises those cases of tickling in the throat, frequently not connected with any ascertainable cause of irritation, either local or reflex. The author stated it as his belief that this tickling was often the earliest symptom of laryngeal phthisis, and that it had been observed to occur on the same side on which pulmonary trouble appeared subsequently. As treatment for these cases, he recommended sedatives, tonics, and change of air.

AFTERNOON SESSION.

The first paper was read by Dr. Beverly Robinson, of New York, "On Laryngeal Affections of Pulmonary Phthisis," in which he called attention to the peculiar pallor of the mucous membrane noticed in these affections. He then pointed out the different causes of aphonia in phthisical laryngitis as being first a change in the muscular tissue of the muscles of the larynx, causing paralysis of the cords; second, anchylosis of the crico-arytenoid articulation, and finally, the ulceration and infiltration of the mucous membrane. The Doctor further stated that ulceration of the epiglottis gives rise to painful deglutition, and that ulceration of the intra-arytenoid commissure produces cough and mucopurulent expectoration. The ulcerations of phthisis, he stated, were characteristic, which character differentiated them from syphilitic ulcerations. He also mentioned papillary growths in the intra-arytenoid space, as a symptom of phthisical laryngitis, which produces paroxysms of cough, but unless they were very large, should not be removed by evulsion, as they were sure to be reproduced within a short time. The paper was concluded with a consideration of the differential diagnosis between phthisical and syphilitic laryngitis, and the author, in this connection, stated it as his opinion, that tubercular disease in the larynx was extremely rare, if it occurred at all. The curability of the affection under consideration depends upon the stage as well as upon the mode of treatment adopted, and that tracheotomy as a palliative measure, in phthisical laryngitis, was perfectly justifiable and frequently indicated.

Dr. W. Porter, of St. Louis, then read a paper on "The Prognosis of Laryngeal Phthisis," which was a plea in support of the assertions made by him and combated by others, that laryngeal phthisis is often curable. The Doctor gave an account of several cases of undoubted laryngeal and pulmonary phthisis which had been cured.

Dr. Frank H. Bosworth, of New York, then read a paper on "Tubercular Ulceration of the Mouth, with Report of Cases." After having given a minute history of several cases of tubercular ulceration of the mouth, pharynx and tongue, and having reviewed some of the literature on the subject, the Doctor gave it as his opinion that tubercular ulcerations in these localities were characteristic, and unlike any other ulceration, that they were the local outbreak of a general dyscrasia, and that they might precede or be contemporary with the lung symptoms.

A lengthy discussion followed the reading of these papers, during which Dr. Smith, of New York, said we should be careful not to mistake catarrhal for phthisical laryngitis. That in his opinion the laryngeal affection in these cases was usually an inflammation of the mucous membrane, dependent upon the general dyscrasia for a cause, and that the appearance of ulceration was a sign that the parts had been irritated. He thought that in advanced cases the prognosis must necessarily be very bad, but that there might be hope for those in the earlier stages.

Dr. Glasgow, of St. Louis, said that he was very skeptical as to the existence of tubercle in the larynx, and then expressed his views as regards the pathology of the tubercular process.

Dr. Roe, of Rochester, said he had never seen a case get well which had progressed to the stage of ulceration.

Dr. Johnson, of Chicago, said that there should be no difficulty in diagnosing laryngeal phthisis, but that in the incipient stage it might be confounded with catarrhal laryngitis, and that in these cases he relied chiefly upon the temperature. In regard to prognosis, he thought it was always grave, and he had seen but one case of laryngeal phthisis get well.

Dr. Shurly, of Detroit, said that the prognosis depended altogether upon the diagnosis, and that he had seen cases of chronic laryngitis resembling phthisical laryngitis with ulceration. In his experience, true phthisical laryngitis was always accompanied with tubercular deposits somewhere in the system, and was always fatal.

In closing the discussion, Dr. Robinson said that the inference to be drawn from the discussion was that there were cases of cured laryngeal phthisis; and, if such, we should treat our patients with that view. Dr. Porter stated that he had nothing further to add; and Dr. Bosworth said that the more gentle the local treatment of such cases the better would be the result.

After this, the session was adjourned till next day, and the members invited to dine, in the evening, with the President.

Second Day.

The session was opened with a business meeting, after the close of which Dr. Louis Elsberg, of New York, read a very interesting paper on "The Histology of Cartilage in general, and of the Thyroid Cartilage in particular." The paper was illustrated with a number of excellent drawings by the author. Dr. Elsberg next exhibited an apparatus for illuminating the larynx, which consisted of a metal cylinder fitted with a bull's eye condensing lens. This cylinder could be used in connection with the lime light, argand gas burner, or student lamp, and gives a very beautiful light. He also exhibited and explained Trauve's galvanic accumulator, for galvano-cautery purposes.

Dr. W. C. Glasgow, of St. Louis, then read a paper on "the Operation for the Deviation of the Nasal Septum," and showed a new instrument for performing the operation of cutting and crowding back into its original position the cartilage, which is afterwards retained there by wooden plugs introduced into the nostril. The instrument, which had been devised by Dr. Steel, of St. Louis, consisted of a pair of forceps, one blade of which was flat, while the other was furnished with several knives, arranged in star shape upon the blade. In operating, the smooth blade is introduced into the obstructed nostril and the cutting blade into the free one: the forceps is then closed, when the knife blades cut through the cartilaginous septum.

During the discussion which followed this paper, Dr. Jarvis, of New York, said that he had divided the deviations of the septum into three varieties, viz., localized anterior, localized posterior, and general deviations, and that he was in the habit of operating for the removal of the localized ones by transfixing them with a needle and then cutting them off with his wire snare.

Dr. Shurly said that he operated by loosening the mucous membrane and then cutting a triangular piece out of the septum.

Dr. Bosworth said that, in his experience, cotton could, with advantage, be substituted for the wooden plugs for retaining the septum in position after the operation.

Dr. Carl Seiler, of Philadelphia, then read a paper on "The Effect of the Condition of the Nasal Cavity upon Articulate Speech," in which he pointed out the fact that partial or complete stenosis of either the anterior or posterior nares could be diagnosed by the sound of speech. He also exhibited a galvano-cautery knife to be used in the treatment of nasal catarrh, in which the two wires were insulated from each other by vulcanized fibre, a substance which is not affected by heat, and which is a perfect non-conductor of electricity.

In the afternoon, Dr. Roe, of Rochester, read a volunteer paper on "Laryngeal Whistling;" and Dr. Glasgow reported a case of paralysis of the abductor muscles of the larynx, of central origin.

Dr. Clinton Wagner, of New York, then read a paper on "Sub-hyoidean Pharyngotomy for the Removal of the Epiglottis," with illustrative case. He gave a minute account of the details of the operation, as it had been performed by him in a case of malignant growth of the epiglottis. In conclusion he stated that the epiglottis was not necessary in the act of deglutition.

Dr. Geo. M. Lefferts, of New York, then read a paper on the question of "Hemorrhage after

Tonsillotomy," in which he stated that hemorrhage after ablation of the tonsils was not frequent, that dangerous bleeding might occur, but that it could generally be controlled by pressure upon the larger vessels or by torsion of the bleeding branch, and that fatal hemorrhage was extremely rare.

A paper by Dr. Jas. E. Sajous, on "Paralysis of the Vocal Cords due to Lead Poisoning," was then read by title, after which the session adjourned till next morning.

In the evening the members of the Association were entertained at a reception given by the Philadelphia Laryngological Society, at the rooms of the Penn Club

Third Day.

The session was opened by the reading of a paper by Dr. William C. Jarvis, of New York, on "Hyperæmia of the Larynx," which was followed by a paper on the comparative value of atomized fluids in the treatment of the diseases of the larynx, in which he questioned the general usefulness of sprays, and suggested a new method of using the spray, which consists in telling the patient to close the lips around the tube, and to breathe through the nose.

Both these papers were discussed together, and the discussion proved to be chiefly technical in character. During the discussion, Dr. Delavan, of New York, exhibited a spray tube for throwing the atomized liquid into the vault of the pharynx, which he thought was superior to the tube in general use.

A paper, by Dr. W. H. Daly, on the "Relation of Hay Asthma to Nasal Catarrh," was then read by title, after which the Association went into private session for the election of officers for the ensuing year.

Dr. F. I. Knight, of Boston, was elected President; Drs. Shurly, of Detroit, and Porter, of St. Louis, Vice Presidents; Dr. Lefferts, of New York, Secretary and Treasurer; Dr. Bosworth, of New York, Librarian; Dr. Harrison Allen, of Philadelphia, to fill a vacancy in the Council. The next annual meeting is to be held in June, 1882, at Niagara Falls.

In the afternoon most of the members went on an excursion, by special train, to Atlantic City, where they were entertained at the Seaside House and the Brighton Hotel, returning to the city about midnight.

MEDICAL SOCIETY OF THE THIRD CONGRESSIONAL DISTRICT OF INDIANA.

Reported for the MED. AND SURG. REPORTER.

The Society met at Jeffersonville, Ind., May 4th, the president, Dr. J. L. Stewart, in the chair. Dr. N. Field read a report from the Committee on Practice.

Dr. C. N. Nutt reported the case of a female patient, aged 49, suffering from double sciatica, to whom one-third of a grain of morphia sulphatis was administered hypodermically.

In less than *one minute* after the needle was withdrawn very alarming symptoms of narcosis supervened. The symptoms lasted for six hours, despite active resorts to restoratives.

Extreme nausea, vomiting, and epigastric distress persisted for five days, when they gradually abated, and the lady advanced to a permanent recovery.

Dr. G. W. Burton, of Mitchell, Ind., next reported on the subject of medical legislation in Indiana, saying that the subject had engaged the attention of the General Assembly for nearly a quarter of a century, that in the last eight years over forty "bills" had been introduced, and in turn, each had failed. He thinks this is due to the fact that the profession is not yet ready for a law upon the subject. The opposition includes unrecognized homœopaths, eclectics, physio-medicals, corn doctors, cancer doctors, itinerants, and a considerable number of "weak-kneed regulars." These were all agreed in opposing everything. Regulars could not and would not agree upon any bill. Indianapolis was opposed to the bill presented by Dr. Hibberd, Chairman of the State Society's Committee. The colleges opposed a law requiring an examination of their graduates. Quite a number wanted nine examining boards, others four, others one, and still others none. Dr. Yancey's bill, of the Senate, provided for nine boards. Dr. McIntosh's, of the House, provided that the county clerk of each township, from the evidence presented, should determine as to the fitness of all applicants, and for such as were qualified, should put the seal of the county on their certificates as evidence thereof. With this great difference in the ranks of the regular profession, it can readily be seen that it is impossible to accomplish anything. If there is to be a law to protect the people of this commonwealth from the great army of "quacks" now infesting every part of it, the regular profession must first agree as to what that law shall be, and then, as a body, demand it.

Dr. W. O. Roberts, of Louisville, reported a dislocation of both hips, in a man sixty-three years of age, the right one in the dorsum of the ilium, and the left in the obturator foramen. The accident was caused by a pile of lumber falling on the man while he was in a stooping position. Reduction was accomplished by Reed's method, practiced *while the patient was upon the floor*. He spoke of the great advantage of Reed's method over that of extension and counter extension. The right limb became paralyzed, which was due to the injury received by the nerve at the time of the accident. But now (two years since the accident) the man is able to walk with the assistance of a cane, and is at present attending to light work in the lumber yard.

Dr. L. S. Oppenheimer, of Seymour, reported a case of xenomenia following spinal injury—atresia uteri—operation. The patient, aged nineteen, began menstruating in her thirteenth year. Two years ago she was struck on the back, in the lumbar region, by a fire shovel; spinal caries set in, resulting in an abscess and in partial paralysis. The menses remained absent until an operation for caries was performed by Dr. J. M. Holloway, of Louisville, and a supporting apparatus applied; after this, whenever the menstrual period returned the patient suffered from cephalalgia, stupor, etc., until profuse epistaxis (vicarious menstruation) set in and relieved the cerebral symptoms. This continued for several days, and

then gradually ceased. Each menstrual epoch has been marked by these phenomena since that time. An examination of the generative organs revealed marked atrophy and atresia of the uterus. I forced an entrance into the uterus by means of a small sound, and maintained it patent by appropriate treatment. The following menstrual epoch came on, beginning with the cerebral symptoms and slight epistaxis, but gradually changing to the generative organs, pelvic fullness and flowing from the uterus. The flow of blood was slight at first, but gradually became more profuse, and in a few days disappeared. The patient now seemed to be in a fair way to recover, but the next epoch brought a reappearance of the epistaxis, etc., and no more blood flowed from the uterus. The liver was found to be considerably enlarged and displaced. After about six months the patient died. The autopsy revealed besides the atrophied uterus and ovaries, and the spinal disease, a liver weighing nine and a half pounds, almost entirely filling the abdominal cavity, and displacing nearly all the pelvic viscera to the left.

Dr. Wm. H. Wathen, being announced by the programme for an oral communication, said that he desired to call the attention of the Society to that fatal form of disease, "cancer of the uterus," from the fact that many of the best practitioners of the country will sometimes treat a patient suffering from cancerous disease of the uterus for months, possibly for one or two years, without a knowledge of the true nature of the trouble, and sometimes without even suspecting its serious character. He wished to impress upon the members of the Society the importance of making a physical examination of women suffering with uterine symptoms. Generally the symptoms of cancer, he said, are sufficiently well marked to attract the attention of the practitioner to an extent that will lead him to make a physical examination of the pelvic organs. Occasionally, however, the symptoms are so masked that the disease may progress to its final stages without the symptoms being sufficiently marked to indicate its gravity. He had met in his practice, in consultation, quite a number of patients under the treatment of the best practitioners of the country, where the symptoms presented, even in a casual examination, indicated that cancer had progressed to a very considerable extent, and in a few instances to an almost fatal degree, the patient all the while under treatment for other ailments.

If physicians would remember the importance of an early diagnosis of cancerous disease, and would make examinations with care when women present themselves suffering from some form of uterine trouble, the nature of the difficulty might be diagnosed often sufficiently early to enable the surgeon to remove the disease and probably entirely cure the patient. He called attention to the fact that nearly all of the latest and leading pathologists teach that cancer is originally of local origin, and finally becomes constitutional by an absorption of the poisonous matter. He claims that this is the only rational theory, in view of the facts now before us, that can account for the course of this disease; and that, this being true, if that form of cancer which involves the cervix could be detected before it had reached the vaginal attachments, or extended to the walls of the uterus and into the cellular structures surrounding, it might be removed by amputation or by the application of caustics, and that numerous cases operated upon in this fashion have been reported to be entirely cured. Of course, in that form of cancer known as sarcoma, which is found occasionally in the body of the uterus, an early diagnosis would be of no great importance, from the fact that the disease is so situated that it cannot be removed without the performance of hysterotomy, a very serious and often fatal operation, which, even if successful, is usually found to have been preceded by such a wide spread disease that other pelvic structures are very soon attacked, conducting the case to a fatal termination.

He emphasized, that while the symptoms that point to the usual form of cancer, epithelioma of the cervix, are nearly identical with many of the symptoms that are observed in inflammations, erosions and ulcerations of the cervix, still, there is generally more pain and the discharge is more watery and acrid.

Granting that the symptoms are identical, they are sufficiently well marked to indicate the necessity of a physical examination, by which the nature of the disease would be detected sufficiently early to admit of its removal.

In many instances the pain is so marked as to be characteristic, but such decided symptoms may not appear until the disease has extended into the cellular tissues surrounding the uterus, so that the disease cannot be entirely removed. He said that, unfortunately, he had met with a few cases where the disease had so far progressed that he could only mitigate the severity of the symptoms and prolong life, an operation, in these instances, being found of great benefit in controlling the otherwise fatal hemorrhage, and the acrid discharges that keep the vulva and adjacent parts constantly excoriated. He related an interesting case where he had operated upon an old lady, 64 years of age, two years ago, in whom the disease had not returned up to this time.

Dr. J. M. Matthews, of Louisville, being announced for an oral communication, spoke as follows: I will relate a case of Verneuil's operation of linear rectotomy, recommended in cases of stricture of the rectum. The ecraseur or galvano-cautery is used by him in performing the operation. Mr. Allingham uses the knife in lieu of both these, and no doubt it is to be preferred, in the majority of cases. I imagine that the former were recommended simply because of the fear of hemorrhage; but if the knife is properly handled, very little hemorrhage will ensue, and if it should, it can be easily controlled. The operation as devised and practiced by Verneuil, for stricture, is as follows: The knife being substituted for the ecraseur, or galvano-cautery, as suggested by Mr. Allingham. The patient is put in the lithotomy position and the finger passed through the stricture. A long, straight knife is then introduced along the finger until the point is fully above the stricture; a firm cut should be made through it, into its whole depth, even to the sacrum, if necessary, and the knife brought out at the tip of the coccyx. The whole stricture must be divided, from the upper edge down to the

coccyx, and through its entire depth. Thus a deep drain is made, from which all discharges freely flow, and as it heals up the ulceration ceases and the stricture is sometimes cured. If the median line is kept the bleeding is but trifling. I have now practiced the above operation in five cases of stricture of the rectum, and cannot recommend it too highly. It cannot be claimed, of course, that all such cases are cured by this operation, as, for instance, those originating from specific causes, but so rapidly beneficial is it that in a few hours night sweats are arrested, and the patient, who seemed ready to die, will really eat, drink, and improve. The wound should be well syringed and the parts kept clean. You will at once perceive the great advantage of this operation in stricture to the oft advised and practiced plan of dilating the same with bougies. The latter proceedure is not only fraught with danger, but requires many months to accomplish a cure, if ever. It certainly is to be preferred to colotomy, in the same trouble, from the fact that colotomy is a formidable operation, disgusting to the patient, and with no promise of cure. It was not, however, for the relief of *stricture* that I desired to speak of Verneuil's operation of rectotomy, but witnessing its very beneficial effects in this trouble I was led to practice it in *ulceration* and *cancer* of the rectum. For this class of unfortunate patients there is little done by the general practitioner, and if, perchance, they fall into the hands of the surgeon, either extirpation of the rectum or colotomy is advised. To my mind, both of these operations are wrong, for either cancer or ulceration; colotomy never did prolong the life of a patient suffering from cancer, one single day. It is accepted as a *dernier ressort*, and that only to relieve pain. If this pain, which is the predominant symptom in cancer and ulceration, can be relieved outside of so dangerous and disgusting an operation as colotomy, it behooves us to know it. I can safely recommend it in these cases, having now practiced it in more than half a dozen such, with entire satisfaction to myself and patient. Of course, no cure is promised here, nor expected. It is simply for the relief of the distressing pain which accompanies these diseases, and is offered as a substitute for colotomy, which is usually done to accomplish the same thing.

The festive features of the meeting were highly creditable to the local members of the profession, and were fully appreciated by the visitors from abroad.

Editorial Department.

Periscope.

On Gastro-Intestinal Dyspepsias.

In a review of a work on this subject, by Prof. Sée, the Paris *Médicale* observes that it is divided into two principal parts, the one theoretical and physiological, the other therapeutical. Mr. Sée assumes, from this principle, that dyspepsias are in the first place chemical operations, and that they can belong to but one order, no matter the organ in which the digestive juice is at fault; in a word, gastro-intestinal dyspepsias are imperfect chemical operations. The digestive organs derive importance from their secretions, and secretion owes its power to the digestive ferments, which are intended for the transformation of the four great divisions of food (albuminoidal, fatty, feculous, and saccharine substances).

A chemical derangement is, therefore, the *sine qua non* condition of any gastro-intestinal dyspepsia. This theory is very ably established and defended by Mr. Sée, and does not exclude the histological elements from participation.

The practitioner having under treatment a case of dyspepsia must, therefore, carefully examine the alterations of the gastric juice. Its degree of acidity; the quantity and conditions of the pepsins; the alterations caused by mucus, or the gastric juice; the physiological modifications caused by an excess of peptones; peptic troubles owing to inanition; the signs indicative of a putrid fermentation of the food; all that greatly simplifies the physiological theory, and hence the treatment of dyspepsias.

A number of the nervous troubles which are met with among dyspeptic patients, such as neuralgias, headaches, palpitations, etc., are considered by Mr. Sée as due to reflex actions; on the other hand, all nervo vascular troubles may, by counter effect, impede the formation of the stomachic juice.

Passing over the differential diagnosis of dyspepsias, we come to the question of treatment.

In order to be rational, the treatment of dyspepsia must rest upon the chemical origines. According to Mr. Sée, the treatment consists in seven principal methods.

The first includes *digestives* and *nutritives*. He studies the effect of chlorhydric acid, of digestive ferments, of pepsines, pancreatines and peptones; with regard to these last his conclusion is that—in obstructions of the upper ducts, alimentation by means of peptones is alone possible—in severe dyspepsias, in incoercible vomitings, peptones are an auxiliary resource we should not neglect.

In the second method Mr. Sée includes *pepsinogenic substances*, which are made up from alkalines and alcohol.

The third method comprises *excitants*, and the author explains the effects of bitters, such as columbo, gentian, quinia, beer, orange, etc., etc., as also of tannin and substances containing tannin, of the strychnias, and of nitrate of silver. There is a method which, for some time past, has attracted much attention; it is the cleaning out of the stomach by means of the gastric probe. Mr. Sée gives its history, and explains when it is indicated, and how it should be used.

The fifth method is composed of *evacuants*,

that is, emetics and purgatives. This is a careful study on evacuants, their mode of action and when indicated.

The sixth method comprises all *absorbing* and *neutralizing substances*, such as magnesia, charcoal, etc. These are but auxiliary agents, and with them the author includes sedative substances, as opium, belladonna, henbane and aconite.

However able and rational the treatment, it would be of no avail, were it not assisted by a regimen. Several chapters are devoted to diet, to the digestibility of nitrogenous food in proportion to its consistency, the amount of water it contains, its volume, its texture, its mode of preparation, and its degree of assimilation.

Mr. Sée likewise studies the effects of non-nitrogenized food, and examines the so-called exclusive regimen.

Among others, the vegetarian system, which, although of ancient origin, is again attracting attention, and having disciples in several countries.

The chemical theory being demonstrated, it would seem that there should be no difficulty in formulating a chemical treatment. Unfortunately this is not the case.

We can give but a very imperfect idea of this important work, which is based upon the teachings of the physico-chemical and biological sciences, and is far in advance of such books as those by Bean, Chomel, Guipon and Nonat.

Sterility and Amenorrhœa.

The following case is reported by Dr. Jugand, in the *Progrès Médicale*, and is not devoid of interest:—

Madame L. is a native of Strasburg, but for a number of years past has resided in Paris, where she conducts a dress making establishment. She is of medium height, and of rather delicate appearance. Her complexion is colorless, and has a dull, yellowish hue, indicative of chloro-anæmia. But she speaks of her health as being generally good. Her appetite is fair, and family antecedents excellent. At the age of 17 a few drops of blood appeared at the vulva, and since then she has never had her courses. She was married when 22 years old, and each month experiences all the symptoms of uterine congestion, pains in the back, in the abdomen on a line with the ovaries, bearing-down pains, febrile movements, etc., etc.

Mrs. L. is anxious to become a mother; she has often sought medical advice, and has tried almost all known emmenagogues, from mugwort to saffron, including rue, spurred rye, etc., etc.

Local treatment, by means of Sitz baths, cold douches, injections and medicated sachets, has not been of any better avail. Finally, of her own accord, she has been taking, for over two years, iron in insoluble pill form, and this has brought on considerable digestive troubles.

It is under those conditions that Madame L. came to us for treatment in September last. An examination of the neck of the womb revealed no abnormal conditions, and digital pressure caused no pain. The hysterometre penetrated without marked difficulty, and furnished the indications common to women who have had no children. Our first advice was to suspend all treatment for a month, recommending only careful hygiene, and well selected but moderate food; to this we added phosphated peptones, so as to assist the somewhat debilitated digestive organs.

A mild diarrhœa supervening, we prescribed citrate of magnesia, in small doses, so as to modify the intestinal mucous membrane; this not proving a sufficient check, we added to it albuminous water as a drink, and, in connection therewith, syrup of citrate of iron, to subdue the chloro-anæmia. We were gratified to find that the diarrhœa ceased, the citrate of iron was well tolerated, and six weeks later Madame L. noticed a few drops of blood oozing from the vulva.

Struck by this coincidence, we immediately placed the patient on a course of albuminate of iron liquor combined with bitter orange peel, as prepared by M. Laprade.

During the following four months the periods appeared regularly, and without pain; they stopped on the fifth, and now Madame L. is on the eve of being a mother.

Methods of Surgical Dressing.

Mr. Wm. Berry, F.R.C.S., observes, in the *Medical Press and Circular*, March 23: while Listerism in surgical practice is *sub judice*, perhaps more especially in private practice, owing to the want of time, help, and appliances, on the part of the general practitioner, it is well, perhaps, that some safe, simple, and effective mode of dressing can be employed.

The examples from hospital practice, afforded by Mr. Sampson Gamgee, of Birmingham, are certainly satisfactory, and will, I think, commend his mode of treatment to the busy practitioner. His *dictum* of rest, drainage, and pressure, if duly carried out, will save much time and trouble, and show results comparable with the antiseptic method.

I have endeavored, through the small means at my disposal in private practice, to carry out this plan, using absorbent wool as dry dressing, proper means of drainage, and firm and even bandaging; so far, am admirably satisfied with the results.

The absorbent wool, which can be obtained either in bulk or in pads, is an excellent material for carrying out this mode of treatment. When applied to a wound it forms a nice, soft covering, takes up any discharges which may escape, and allows the parts to be undisturbed till the dressings are saturated and uncomfortable. If the discharges be fœtid and unhealthy, the wool can be made antiseptic by means of terebine, salicylic, carbolic or boracic acid.

Dressings of this material are easily carried and applied, they need not be disturbed for some days, unless the thermometer indicates some disturbance of the system or the dressings become saturated, then the covering should be removed, the wound cleansed, and a renewal of fresh dressings made.

In large wounds and in chronic abscesses it is always better to insert a drainage tube, so as to

allow of the free escape of fluids which may collect, then, a sufficient covering or pad of absorbent wool, firmly and evenly bandaged on with an ordinary roller, will constitute a light and compact dressing, which may remain undisturbed until one of the conditions mentioned above necessitates a change.

I would here mention the importance that should be attached to the indications of the thermometer in all surgical cases; for long before either pulse, tongue, facial expression, or pain in the part show any disturbance, the thermometric rise will indicate something wrong; then the dressings should at once be removed and the wound examined.

The "Epidemic Constitution of the Atmosphere."

This mysterious old phrase is thus explained in the National Board of Health *Bulletin*, by Dr. Geo. M. Sternberg, U.S.A.:—

The fact, observed by myself, that during the summer months the mud in the gutters of New Orleans possesses an extraordinary degree of virulence, shows that pathogenic varieties of bacteria are not alone bred in the bodies of living animals. The more I study this subject the more probable it seems to me that in this direction lies the explanation of many problems which have puzzled epidemiologists, and that the sanitarians are right in fighting against filth as a prime factor in the production of epidemics—a factor of which the *rôle* is easily understood, if this view is correct.

The presence of septic organisms, possessing different degrees of virulence depending upon the abundance and kind of pabulum furnished them and upon meteorological conditions more or less favorable, constitutes, in my opinion, the *epidemic constitution of the atmosphere* which wise men were wont to speak of not many years ago as a cloak for ignorance. It must be remembered that the gutter mud of to-day, with its deadly septic organisms, is the dust of to-morrow, which, in respiration, is deposited upon the mucous membrane of the respiratory passages of those who breathe the air loaded with it. Whether the peculiar poison of each specific disease is of the same nature or not—a question which can only be settled by extending experimental investigations in the future—it is altogether probable that this factor often gives a malignant character to epidemics of diseases which, uncomplicated, are of a comparatively trivial nature.

Reviews and Book Notices.

BOOK NOTICES.

Dyspepsia; How to Avoid It. By Joseph F. Edwards, M.D., Author of "How a Person Threatened or Afflicted with Bright's Disease Ought to Live," "Constipation Plainly Treated and Relieved without the Use of Drugs." Philadelphia: Presley Blakiston, 1012 Walnut St., 1881. Cloth, 12mo, pp. 87. Price 75 cents.

Popular hygienic works are getting more and more in demand, and are, perhaps, contributing more than any other single agency to the spreading of sound and useful knowledge of sanitary matters and just appreciation of the value of the prevention of disease. The book before us will recommend itself to the American public, who are proverbially a nation of dyspeptics. It is divided into four chapters, on food, digestion, how to cook food, and how and what we ought to eat. The information it contains will, in the main, be found valuable, and most individuals would undoubtedly be benefited by following the precepts laid down therein. We think, however, that the author goes a little too far when (page 39) he asserts that a piece of pork containing trichinæ may be eaten with impunity and with as much safety as a fresh-laid egg, provided it be first thoroughly cooked. This assertion is contrary to the opinion of those who have carefully investigated the subject (see Rep., vol. xliv, page 353), and dangerous in the extreme, when we consider how vague is the idea of thorough cooking among the laity. Some novel and startling psychological suggestions occur in the first chapter, on food; thus, on page 19, the author asks: "Is it too visionary, to imagine that some of the particles of brain tissue which, in the mind of Julius Cæsar, originated and worked out the details of military campaigns which resulted in making Rome the master of the world, may, after centuries of wanderings and vegetable life, and residence in minds of inferior calibre—poor pasture, as it were—finally have been eaten by and assimilated into the brain of Napoleon Bonaparte, and, meeting there with conditions and surroundings like to those of their ancient Roman home, planted in good and well-manured brain soil, they may have grown vigorously, labored with some of their ancient energy, and enabled Napoleon, through their agency, to make France mistress of Europe?" We think it rather visionary.

The Sanitary Care and Treatment of Children and their Diseases. Being a Series of Five Essays, by Drs. Elizabeth Garrett Anderson, Samuel C. Busey, A. Jacobi, J. Forsyth Meigs, and J. Lewis Smith. Prepared by request of the Trustees of the Thomas Wilson Sanitarium, of Baltimore, Md. Boston: Houghton, Mifflin & Co. The Riverside Press, Cambridge, 1881. Cloth. 8vo, pp. 309. Price $2.50

These essays, being the result of vast experience, profound thought and careful preparation, deserve a wide circulation. Want of space, however, precludes the possibility of our giving them the full attention in this review which the im-

portance of the subjects and the able manner in which they have been treated merit. Dr. Elizabeth Garrett-Anderson, of London, England, in discussing the question, *how can children in a city be kept healthy*, finally comes to the sad conclusion that, "after public and domestic hygiene has done its best, city life will always be full of special risks to children of the poor, and that philanthropic efforts cannot do very much directly toward diminishing those risks." "It can do something," says she, "but it must be mainly through the parents, by improving their knowledge of what the children need, by raising their standard of comfort, and by deepening their sense of responsibility." *The Mortality of Young Children; its Causes and Prevention*, is the title of one of the essays, of more than ordinary scientific merit, prepared by Dr. Samuel C. Busey, of Washington, D. C., in which the author points out the influence of climate, density of population, poverty and ignorance, alimentation, etc., on infant mortality. Dr. A. Jacobi, of New York, gives his views, which are based on the experience of a quarter of a century, *on the improvement of the condition of the poor and sick children;* and Dr. J. Forsyth Meigs, of Philadelphia, presents *observations upon the sanitary care and treatment of children and their diseases.* The subject chosen by Dr. J. Lewis Smith, of New York, is essentially the same as that of Dr. Busey, viz.: *causes of the great mortality of young children in cities during the summer months, and the hygienic measures required for prevention.* The publication of these essays in book form will put them within reach of those interested in alleviating the sufferings of city children, and though the work, perhaps, contains nothing that is new, yet no one can fail to receive many valuable suggestions from its perusal. It may be had in this city, from Messrs. Porter and Coates.

The Diseases of Children. A Practical and Systematic Work for Practitioners and Students. By William Henry Day, M.D., Physician to the Samaritan Hospital for Women and Children, etc., etc. 2d edition, rewritten and much enlarged. Philadelphia: Presley Blakiston, No. 1012 Walnut street, 1881. 8vo, pp. 752. Price, Cloth, $5.00; Sheep, $6 00.

This work, the author informs us, is the outcome of private and hospital practice extending over a lengthened period, and in its preparation he has relied on clinical experience rather than on theories. After a few introductory remarks on the study of children's diseases, their special characters and peculiarities, the management of children during growth and development, the importance of attending to the constitutional rather than the local state, etc., etc., a chapter is devoted to milk diet and hygiene, in which the composition and relative value of various kinds of milk and other substances used as food for children is given, and other hygienic and remedial agents, as air, exercise and sleep, bathing and medical preparations ordinarily given to infants and young children, are discussed. Diseases are next considered in their natural division of acute and chronic, after which each group of diseases and individual affections peculiar to childhood are taken up for special consideration. The classification of diseases adopted by the author is after the method sanctioned by modern pathologists, and the treatment advocated will be found to be fully up to the most recent views of authorities in this department. A list of prescriptions are appended, in the arrangement of which one certain broad principle, as regards dose and combination, has been kept in view, leaving the details to be varied at the discretion of the practitioner. We heartily recommend this book to the profession, as a safe and reliable guide in the department of which it treats.

Medical Electricity: A Practical Treatise on the Applications of Electricity to Medicine and Surgery. By Roberts Bartholow, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College, of Philadelphia, etc. etc. With ninety-six illustrations. Philadelphia: Henry C. Lea's Son & Co., 1881. Cloth, 8vo, pp. 262. Price $2.00.

The object of this work is fully set forth in the author's preface, viz., to furnish students and practitioners with a suitable text-book, neither too voluminous nor too scientific, yet sufficiently complete to embrace the whole subject of Medical Electricity, and so simple in statement as to be easily understood by students previously unacquainted with the subject. The book is divided into six parts, treating severally of Electro-Physics, Electro Physiology, Electro-Diagnosis, Electro-Therapeutics, Electricity in Surgery, and Thermo-Electricity. Medical Electricity has made rapid advance and gained much favor, both with the profession and the public, during the past decade, and no one absolutely ignorant of the uses of this powerful agent can longer be considered properly armed and qualified to combat disease. Though there are, as the author admits, many excellent works on the subject, we think none better meets the needs of the general practitioner than the one before us.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3 20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3 20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

RECENT STUDIES ON FOODS AND DRINKS.

As so many questions in health and economy turn on foods and drinks, the more recent studies on these subjects have a wide interest. Every sanitary reformer starts out with a theory of his own, which, as a rule, he is more anxious to make good than to submit to impartial examination. With the growing cost of the food supply, many advocate the advantage of a vegetable diet as equally nutritive, less stimulating, and cheaper. It is no doubt, in a measure, a question of climate, habit, temperament and race; but taking temperate climates, Prof. BOUCHARDAT was probably right when he said that nations are more energetic in proportion as they consume more animal food.

In a letter in an English contemporary, Dr. C. R. DRYSDALE, of London, quotes some of the latest experiments to test the relative values of animal and vegetable foods. They are of sufficient value to warrant transferral to our pages.

Professor HOFMANN gave to a servant of his 1000 grams of potatoes, 207 grams of lentils, and 40 grams of bread. On an average of six days, it was found that 356 grams of the solid matter were digested, 116 remaining undigested; 38.7 of nitrogenous matter had been digested, 41.4 undigested; 263.8 of starch digested, and 28.2 not. It would here appear that not even one-half of the total albuminous matter of this vegetable diet had been digested in this experiment.

The same man was then given 390 grams of lean beef daily, 126 of pure fat, and 40 grams of flour. The result was that 221.8 grams of solid matter were digested; 33.6 undigested; 73 of albuminous matter were digested, and 16.9 undigested; 124.1 of fat were digested, and 4.9 undigested. Thus, animal food was shown to be much more digestible than vegetable, in this experiment of HOFMANN.

Dr. C. MEINERET, in his work, "Die neueste Ernährungs Theorie," gives the loss of nitrogen in solid excreta, expressed in percentage of the total nitrogen contained in various substances. In meat that loss he found to be only 2.6; in eggs, 2.6; in milk and cheese together, 2.9 to

4.9; in milk alone, 7; in maccaroni and gluten, 11.2; in maccaroni alone, 17.1; in peas, 27.8; in black bread, 32; in potatoes, 32; in carrots, 39; in lentils, potatoes and bread, taken together, 47; in lentil flour, 8.2; in whole lentils, 40.2; in celery, cabbage, and carrots, 31; in Hosford-Liebig's bread, 32.4; in rye bread, 22.2; in very black bread, 42.3; in white wheaten bread, 19.9; in mixed food with meat (fourteen days), 18 to 12. White bread is, say MEYER and RUBNER, far more digestible than brown rye bread.

RUBNER took 1172 and 1435 grams of meat daily (more than 2 pounds), and yet all the albuminous matter except 2.5 per cent. was digested; and when 21 eggs were taken daily, 2.9 per cent. alone of the albumen was undigested. FLUGGE took daily 1 litre of milk, 500 grams of meat, 150 grams of wheaten bread, and 68 grams of butter, and found that 94 per cent. of the nitrogen was absorbed, and 95 per cent. of the fat. When he took a diet chiefly vegetable, he had only 85.3 per cent. of the nitrogen absorbed, and 88.7 per cent. of the fat.

All this points to the great value to a nation of mutton, beef, pork, and other forms of meat diet.

The question of the addition of alcohol to diet is tending more and more to a settlement in the sense that distilled spirits are probably injurious, while wines and beers, in moderation, are innocuous, or slightly advantageous. A careful study of the effect of the "spirit ration" in the British army was lately made by a writer in the British *Medical Journal*. His conclusions were as follows:—

1. Spirits are not an absolute necessity in the field.
2. Given before or during a march, or work of any description, they are nearly always calculated to do harm.
3. The only case in which exception need be made to the above rule is, when men are near the end of a long and fatiguing march, which it is necessary should be accomplished. Then the issue of a spirit-ration may probably supply the necessary stimulus for completing the work; but it must be on the condition that no further work shall be demanded until after a sufficient period of repose.
4. The issue of a ration at night, when work is done, may be useful as a sedative, and in inducing calm and refreshing sleep.
5. Under any of those circumstances, the ration ought not to exceed two ounces and a half (half a gill) of spirits—equal to one ounce and a quarter of alcohol; and it ought to be given well diluted with water—hot, if possible.

Even in cases where its utility is, with limitations, admitted, it is still a question whether extract of meat might not be better, as it certainly would be attended with less chance of evil result, should it not accomplish the immediate end contemplated. Admitting, however, that in cases where rapid stimulus is required, alcohol is more useful than any of the proposed substitutes, there seems to be no valid ground for continuing its issue on campaigns as a regular ration. It would be better to carry it as an extra, and only issue it by the advice and with the concurrence of the medical officer.

In other words, it should be removed altogether from the list of articles of ordinary consumption.

This conclusion will undoubtedly be approved by the large majority of sanitary students. The alcohols in most spirits are, in equal quantities, much more injurious than those in wines; and their more concentrated forms add to their bad effects.

NOTES AND COMMENTS.

The Failure of Pilocarpin in Diphtheria.

We cannot but regret to announce that the more recent trials of pilocarpin, advocated so forcibly by Dr. Gutmann as almost a specific in diphtheria, indicate that it is of no use at all in that disease. Dr. Joseph Schmid, in the *Wiener Med. Presse*, No. 15, 1881, says, after a full trial, he has found it "generally wholly useless, often decidedly injurious." In serious forms of the complaint, he actually believes the unfavorable termination was hastened by his use of the drug. In the lighter catarrhal forms the symptoms were not visibly ameliorated by it.

Some Recently Discovered Medicinal Plants.

If a very little of what is heralded of the medicinal virtues of plants turned out true, it would be a most gratifying fact. However, it is well to record all for trial.

Hieracium Venosum. Observations are given by Dr. W. Stump Forwood, in the *Quarterly Transactions of the Lancaster* (Pa.) *Med. Society*, April, 1881, to show that this may prove of value in phthisis. At least, it seems to have a well deserved reputation for that disease among cattle. The infusion is used.

Euphorbia Villosa. In the Ukraine and Gal-

licia, this plant is said to be regarded as an unfailing remedy against hydrophobia, provided it is taken within five or six days of the infection. Unusually good evidence seems to be in its favor, (*Allg. Med. Cent. Zeitung*, March 26th, 1881).

Convalaria Majalis. Clinical and physiological experiments with this herb are reported in the *Centralblatt für Klin. Med.*, by Dr. Bojojawlensky and Troitzky (No. 47, 1880; No. 1, 1881). In organic heart disease its effects equal those of digitalis; the urine is increased; serous deposits are rapidly absorbed; nervousness is diminished; cumulative effects were not observed.

Uterine Hydatids in Virgins.

A question of considerable interest was lately discussed before the Dublin Obstetrical Society, to wit, whether a woman could expel uterine hydatids—in other words, be liable to "molar pregnancy"—without sexual connection. Dr. More Madden maintained this to be possible. He thinks the unimpregnated ovule may be arrested in its passage through the uterus, and there undergo a vesicular degeneration or other form of abnormal development. The President, Dr. John A. Byrne, dissented, believing that vesicular moles had not been observed in virgins. He granted, however, that substances not unlike these are occasionally expelled from the virgin uterus. These are not true vesicular chorionic degenerations, as this is always a product of conception.

Suggestions in Toothache.

At the last meeting of the Odontological Society, of Great Britain, Mr. Stocken read a paper on "The Value of Certain Remedies in the Constitutional Treatment of Inflammatory Conditions of the Vascular Tooth-Structure, and of Neuralgia arising therefrom." The remedies to which Mr. Stocken specially directed attention were chloride of ammonium, sulphide of calcium, and gelseminum. He had selected them because their action was not so generally known as that of many other agents. He gave a full description of the therapeutic effects of these drugs, indicating the class of cases in which each would be likely to be most serviceable. His conclusion was that, in simple neuralgia of the fifth pair, gelseminum, either with or without aconite, would effect a cure or, at least, afford considerable relief. If the pain was due to congestion or inflammation of the pulp or periosteum, he would prescribe also chloride of ammonium. While in chronic periostitis with suppuration, sulphide of calcium gave results which were in the highest degree satisfactory, cutting short the attacks in the most remarkable manner. He was of opinion that dental surgeons do not generally give sufficient attention to the constitutional treatment of the cases under their care.

Painful Effects of Color.

The painful effect of light on the eye in many diseases is well known; that certain colors exert a similar effect on healthy eyes occasionally is less familiar, and is commented on by Dr. Von Hasner in the *Centralblatt für Augenheilkunde*, No. 1, 1881. One patient could not bear to look at white objects, another at red, another at blue. If persisted in, headache, giddiness, sick stomach and vomiting were brought on. This condition, we believe, is by no means an uncommon one in certain lesser degrees, but we do not think it has received special study from ophthalmologists. As the eyes were normal or nearly so, the cause of the defect is probably cerebral.

The Duration of Pregnancy.

A paper in the St. Petersburg *Med. Wochenschrift* (quoted in the London *Medical Times and Gazette*), by Helen Idelson, M.D., an intelligent lady physician, states that she found that of 4370 patients in Prof. Horwitz's Obstetrical Clinic, only 488 could furnish the requisite data for the determination of this question—viz., the exact date of the last day of the last menstruation, and the maturity of the fœtus. After showing the great differences which prevail in various animals, and the great differences between the maximum and minimum admitted by authors in woman, she states that it results from her own researches that the average period was 278.8 days, viz., a minimum of 226 and a maximum of 328, or a difference of 102 days.

She sums up the results of her investigations as follows: 1. The duration of pregnancy amounts to 278.8 days, or nearly forty weeks. 2. The sex of the infant influences the duration, this being longer in female infants. 3. The heavier the child the longer is the duration. (?) 4. The duration is longer in multiparæ than in primiparæ. 5. The younger the woman the longer is the duration. 6. The duration is longer in married than in unmarried women. 7. The first movements of the child are felt, on an average, on the 135th day, but later in primiparæ than in multiparæ.

Special Reports.

NO. XI.—INSANITY

It must be confessed that

The Causes of Insanity.

have been investigated in a very unsatisfactory manner. Causes which in one report stand out prominently are hardly mentioned in another. For instance, in American reports, genital excitation and disease vary from 14 per cent. to zero in patients taken from the same class and country. Evidently this great difference depends on the "personal equation" of the physician in charge, and not on the patients. In fact, all such causes are generally predisposing rather than efficient. This is now becoming recognized. After referring to the alleged causes of insanity in the patients admitted into the Lancashire, England, County Asylum, during 1879, Dr. Cassidy, the medical superintendent, argues that there is an anatomical and physiological substratum beneath these so-called causes which it is greatly more difficult to reach. For instance, among 13,309 admissions into asylums in England and Wales in 1878, the causation of insanity was attributed in 1951 cases to intemperance in drink, in 78 cases to pregnancy, and in 102 to fevers. If we consider the extent to which these three so-called causes flourish in England, it seems fair to conclude that they have less to do with the insanity with which they are occasionally associated than has the weak and unstable nervous organization upon which they act.

In a communication to the third Italian Phreniatic Congress, held last September at Reggio-Emilia, Dr. Andrea Verga states that, based on the official census made the last day of December, 1877, he has been able to ascertain that, among the different causes of insanity in Italy, pellagra appears in 8.88 per cent. of the cases; diseases of fœtal life and early infancy in 7.77 per cent; derangement of the female sexual organs, and related to the maternal life, in 6.96 per cent.; epilepsy in 7.73 per cent. of the males, and in 5.51 per cent. of the females, amounting to a net total of 6.68 per cent.; alcoholism in 3.92 per cent.; venereal and other excesses in 3.73 per cent. among males, and 1.16 per cent. among females. Dr. Verga further points out the greater frequency of mental diseases among physicians, and the increase of general paralysis.

Relation of Mental Disease to Sexual Irregularities.

The intimate relationship between the mental and sexual life and their reciprocal actions, are the subject of a well-written article by Dr. A. J. C. Skene, in the *Annals of the Anatomical and Surgical Society*, of Brooklyn, vol. ii, No. 11. His investigations are confined chiefly to the female sex, but he justly remarks of both sexes, that "failure in reproduction (more accurately, in reproductive acts) always causes more or less disappointment and mental depression in those who are naturally of sound mind and body." This is, of course, aggravated where an insane neurosis is present, or where a disease of either organ heightens the mental sensitiveness. As he says:—

Clinical observation affords ample proof of the truth of these statements. An ovarian or uterine hyperæmia arising from extrinsic causes first deranges the function of these organs, and, secondarily, produces perverted brain action in the form of irritability, mental depression, excessive interest or apathy. Every physician is familiar with the groundless fears, the melancholia and mental irritability which so often are associated with diseases of the sexual organs. It is equally well known that evil influences direct the mind to the sexual organs and excite them to premature, and hence imperfect, functional action. In adult life, also, the brain which is badly organized and unqualified by culture for its office of guarding and protecting the physical functions, may so influence the sexual organs as to make their periodical excitation and congestion continuous and abnormal.

This is a theme on which much might be written with profit.

Cerebrology of Criminals.

A curious observation has been made by Dr. Moritz Benedict, of Vienna. He published a book about a year ago, *Anatomische Studien an Verbrechergehirnen*, in which, among other notes, he states that in nearly one half of the brains of persistent criminals the superior frontal convolution is not continuous, but is divided into four sub-convolutions, analogous to the disposition of the parts found in predatory, carnivorous animals. In a recent paper (*Centralblatt für Med. Wiss.*, November 13th, 1880), he argues that much of moral perversity may and must be the result of this deflection of the cerebral organs from the normal type, producing, as it necessarily would, other arrangements of cerebral nutrition, and hæmostatic relations. It cannot be fortuitous that the mental characteristics of the most perverse criminals, and also the cerebral anatomy, both resemble those of wild beasts; this double analogy must be one of cause and effect.

Insanity as a Disease.

Some sagacious observations on this point may be found in the *Report of the Commissioners of*

Lunacy in England, 1880. One extract will not be out of place:—

"The disease of lunacy, it should be observed, is essentially different in its character from other maladies In a certain proportion of cases the patient neither recovers nor dies, but remains an incurable lunatic, requiring little medical skill in respect to his mental disease, and frequently living many years. A patient in this state requires a place of refuge, but his disease being beyond the reach of medical skill, it is quite evident that he should be removed from asylums instituted for the cure of insanity, in order to make room for others whose cases have not yet become hopeless. If some plan of this sort be not adopted, the asylums admitting paupers will necessarily continue full of incurable patients, and those whose cases still admit of cure will be unable to obtain admission until they become incurable, and the skill and labor of the physician will thus be wasted upon improper objects. The great expense of a lunatic hospital is unnecessary for incurable patients; the medical staff, the number of attendants, the minute classification, and the other requisites of a hospital for the cure of disease, are not required to the same extent. An establishment, therefore, upon a much less expensive scale, would be sufficient.

Mental Contagion.

A most extraordinary notion on the subject of insanity was advanced by that distinguished though erratic writer, Dr. Benjamin W. Richardson, in a paper read before the Exeter Sanitary Institute, and part of which we find in the *Scientific News*, February, 1881. His words are:

"Go into the wards of a lunatic asylum, and notice among the most troubled there the odor of the gases and the vapors they emit by the skin and the breath. That odor is from their internal atmosphere, their nervous, ethereal emanation. They are mad up to suicide or murder, or any criminal folly. Can it be otherwise? They have secreted the madness; they are filled with it; it exhales from them. Catch it, condense it, imbibe it, and in like manner it would madden any one."

This absurd hypothesis is not new, but is taken from the visionary theories of insanity set up by the Germans, Jäger and Dunstmaier, a few years ago, and which, at the time, many took to be a huge joke—as we are not yet sure but that it was. It is a forced expression of what is well known among alienists as "mental contagion." In his *Contributions to Psychiatry*, Dr. James G. Kiernan, of New York City, has lately given a number of examples of this fact, and made some useful practical applications of it. Mental contagion is not a term that is easily defined, and to many the phrase itself will seem a paradox; but those who know the writings of Fabret will perhaps recall his philosophical study of *folie à deux* (madness of two), and the remarkable suggestiveness of his literary treatment of one of the obscure themes of the medical professor, printed some years ago in the *Annales Medico Psychologiques*.

In a general way, the fact that certain forms of insanity, or rather certain hallucinations, are communicable, has not escaped common observation; and this contagiousness even extends to certain involuntary and automatic movements, the delusion of special form of nervous paroxysm being created by one person as the active agent, and imposed upon the other party to the malady as a passive recipient. Such movements are often contracted even by asylum attendants, from contact with their charges. This form of insanity, says Dr. Kiernan, is more common among women than men, and always presents the same group of symptoms developed under similar conditions and circumstances. It consists in the communication of an insane intellectual conception from one mind to another, or an insane movement from one nervous system to another. Sometimes when patients are associated with each other, identical delusions develop themselves in each simultaneously.

The point in controversy is not as to the existence of the form of disease, but as to its comparative frequency. Dr. Kiernan, from close observation of a large circle of the insane, concludes that contagious delusions are relatively common in our asylums, and draws from their prevalence an argument in favor of isolating insane patients from each other, and thus improving their mental condition by limiting the spread of insane ideas. He appears to think that the prospect of recovery is often sacrificed by exposure to communicable delusions, which, with the tendency of insanity to nurse *idées fixés*, seize the enfeebled, but highly excited, imagination of the victim with a grip so strong as to break down the last vestige of self-control.

The general view of the medical profession has been that mental contagion is only possible in very exceptional instances. Dr. Kiernan's observations are at variance with this theory, drawn from the memoirs of Tuke, Fabret, and others, and involve the presumption that non-contact of the insane with each other is sometimes a factor essential to recovery.

Treatment of the Insane.

The "non-restraint" or Conolly system of treating the insane is certainly on the increase everywhere. From such a remote field as British Guiana we may bring evidence of this. The last report of the Superintendent, Dr. Grieve, states that the asylum contains upwards of 200 patients, of a

mixed and rather unruly class, yet restraint is never had recourse to. Fortnightly dances are held, a good band has been formed, and picnics and concerts are provided. Further experience has confirmed Dr. Grieve in the opinion that suitable and interesting occupation is the main element to be held in view in the moral treatment of insanity, combined, of course, with constant kindness and consideration for the sufferers. The more skill required in the work and the greater the demand it makes upon the mental powers, as long as it is not beyond the grasp of the insane, the better the results. This is shown by the fact that the carpenter shop turns out more recoveries than any other part of the asylum.

Another reform—for we are inclined to regard it as such—is the appointment of female alienists to take charge of the female wards of insane asylums when such persons, of sufficient competence, can be secured. The recent discussions at the Pennsylvania State Medical Society show that very many thoughtful men in the profession coincide in this view; and the objections to it come rather from general opposition to female practitioners than from a doubt as to their special fitness for the position.

(*To be continued.*)

Correspondence.

Remarks on Intermittent Fever.

Ed. Med. and Surg. Reporter:—

In reply to the second question of S. S. F., of Pennsylvania, in No. 15, vol. xliv. of Medical and Surgical Reporter, I will record some clinical experience which I have for some time contemplated reporting through your journal. The question, what is the best treatment for preventing the return of intermittent fever, has frequently puzzled me, and oftentimes, after using the best treatment known to me, the fever would return all the same.

The first few years of my professional life I practiced in a malarial district in Mississippi, and while there was called upon to treat malarial fever in its various forms. I gave all cases the usual treatment, that is to say, quinine or arsenic, followed by iron and bitter tonics. To this treatment most cases would respond and get well nicely, giving the physician confidence in his remedies, and the patient faith in his doctor. But there are other cases which do not so readily yield to treatment, and it is to these that I have directed some clinical experiments. I will not give details of experiments, but report from my practice a few cases of chronic malarial fever, vulgarly called seven-day chills. In one family I had four cases of fever which served to keep me in daily employment till I got almost ashamed to be seen going to that house. All of them seemed to be amenable to treatment, and would yield readily to quinine after a single paroxysm. But I would hardly discharge one case before I was called to another, and when he was apparently well, the third would be attacked, and so on in turn. These attacks would return, although they took iron and quinine in tonic doses, continuously for some time. A professional friend suggested the propriety of giving iodine in small doses, which I did with the happiest effect in some of the cases, but the others could not tolerate the iodine except in homœopathic doses, from which, of course, I could expect no beneficial result. The iodine in these caused irritation of stomach and alimentary canal. For them I ordered removal into the piny woods, which I believe would have been the best prescription for them all at the beginning. But such advice is not always practicable. After treating these cases and noting that those who could tolerate the remedy made a good recovery, I had some faith in iodine; but the question then arose, how can I administer it without producing the ill effects mentioned above?

The question was finally solved by an article I read a year or two ago, in the Reporter, on the administration of iodine in, I think, some ovarian trouble. The writer used the iodide of starch, made according to Buchanan's formula, which consists of twenty-four grains of iodine to the ounce of starch, *vide* United States Dispensatory Appendix. He stated that in this form patients could take large doses of iodine without any irritating effect. After reading this article I had more confidence in my ability to combat the tendency to return in intermittent fever, and was anxious to give this preparation a trial. The first patient to whom I gave iodide of starch was a young man who had been under the treatment of several good physicians, and had taken, I suppose, nearly every known antiperiodic. But the chills would return every three weeks. I prescribed teaspoonful doses of the iodide three times a day. He passed over his time without any symptoms of a return; but subsequently had another chill and fever and was again given the iodide. He was under my observation for several months after, and showed no disposition to relapse.

I will report only one more case treated with the iodide. The patient, a man, had chills and fever for several months. Could break them with quinine, but he would invariably have a return of them on the seventh or fourteenth day. Patient also gave a history of syphilis and complained of pains in his bones, which were so intense at night as to interfere with rest. After taking one bottle of iodide of starch he returned to have his prescription renewed, saying the medicine was as good for syphilis as for chills. He had no return of his malarial trouble.

My method of administering this preparation is, to give a teaspoonful in water three times a day till one ounce has been taken, and then discontinue till three or four days before the expected attack, when I order another ounce to be taken in the same manner. My experience with iodide of starch is limited, but I think will justify any one in trying it, after failing with all other remedies.

The Use of the Lancet.

Ed. Med. and Surg. Reporter:—

I have a bit of a confession to make, and also a request. I confess being so much of an old fogy, that for twenty years I have carried the *deadly thumb lance* in my pocket, and, what hurts me most, have not used it as often as I ought. During the four years of my pupilage, I saw my preceptor use it once only. For two years after graduating I did not use it at all. Since then I have used it more and more each year, and can truthfully say, that I have never seen a single bad effect from its use; but have often had to lament in sackcloth and ashes that the prejudice of patients, or the opposition of a consultant, has compelled me to witness many a death which might have been avoided, and many a long convalescence which might have been shortened, by an early and free use of the lancet. My fogyism extends even to the use of calomel in many acute inflammatory diseases. The request mentioned is, that some vigorous writer (or rather thinker) would do for calomel what Dr. Corson is doing for the lancet. It is a belief that fire will never melt out of me, that a proper use of these two agencies would completely cure many men and more women of acute inflammations, who, under the expectant and dish-water treatment, only so far recover as to be thereafter daily reminded that it has left them a legacy of which they cannot dispose. In the Reporter of April 30th Dr. Stinson asks "When bleeding is indicated, what practitioner will refuse to resort to the lancet?" Why, Dr., that is just the very point. Nineteen out of twenty fail to see the indication; and the chances are vastly in favor of the twentieth one being afraid to act in opposition to the *great minds* of the profession.

Quinquinia—A Correction.

Ed. Med. and Surg. Reporter:—

Allow me to correct an error which has crept into my brief communication on Quinquinia, in your journal for April 9th. I am made to say that in five of the hospitals and dispensaries of Chicago notes have been kept of cases of intermittent fever and other malarial affections treated by this remedy, of which, *four* were of intermittent fever. It should have read, *forty-one.* I used numerals, and the one (1) after the four (4) was omitted. Four cases, would certainly have been a small number on which to predicate a conclusion, even in these days of rapid generalization. I may say that, since my previous note, I have had a conversation with Prof. Bartholow, of the Jefferson school, upon this subject. He tells me that, before leaving the West, he gave Quinquinia an extensive trial, and found it quite as effective as quinine, in the treatment of all affections dependent upon malarial poisoning; in fact, sometimes succeeding when the latter failed. This fact, together with its comparative cheapness, makes it, in his opinion, perhaps, the most useful derivation of cinchona we have yet obtained.

Metastatic Parotiditis.

Ed. Med. and Surg. Reporter:—

"Assuming, as it undoubtedly does, a form both epidemic and contagious, would it not be well to give it a distinct classification as a disease, and call it metastatic parotiditis, robbing it of its terrors as well." The above extract is from the Medical and Surgical Reporter, of May 7th, taken from a communication by Dr. Charles H. Miller, of Peabody, Kansas. We have here, at this time, a similar epidemic, and it has been present for more than twelve months. The orchitis has been present in a majority of the cases, and exceedingly annoying, and in many instances accompanied by great nervous prostration, and a typhoidal condition of the system. "I change place," may continue as the "battle ground" between the humorist and the solidist for years to come, if such parties now exist; but these theories settle nothing. The specific poison affects the facial salivary group of glands, and pancreas also, in a very marked manner, and, perhaps, finds its way to the testicles, through the same channel, lymphatics, in the same manner as other poisons.

Wm. M. Laurence, M.D.

Batesville, Ark., May 17th, 1881.

News and Miscellany.

The International Medical Congress.

It is anticipated that not less than 2000 foreign medical practitioners will visit London next August, on the occasion of the International Medical Congress to be held in the early part of that month. It is almost certain that in point of attendance, variety of attraction, and extent of opportunities for observation, the London Congress will far surpass any of its predecessors.

By the change in the Presidency of the College of Physicians, Sir W. Jenner becomes *ex officio* Chairman of the General Committee of the Congress, a post, the duties of which have up to the prssent time been discharged by the Chairman of the Executive Committee, Sir Risdon Bennett, M.D.

The International Medical and Sanitary Exhibition.

This is to be open the same time as the International Medical Congress in London. A large number of American exhibitors have already announced their intention to be present, and have applied for space. A plan of the exhibition building has been made, and each exhibitor will have a portion of the plan sent to him with his exact position marked thereon, so that all confusion at the last will be avoided. The committee will receive applications up to the time of the final allotment of space, which will be proceeded with on the entire completion of the plans. The claims of late applicants will, of course, be considered only after those who have already applied have been finally dealt with.

Soluble Compressed Hypodermic Tablets.

The uncertainties attending the use of solutions for hypodermic injections have been well

set forth by Gubler and other writers. To overcome them Messrs. John Wyeth & Bro. have prepared, with great pharmaceutical skill, what are called "Hypodermic Tablets." These are quite small, readily soluble when required, insure entire accuracy in the size of the dose, and also that the drug is well-preserved and active. They have been used with satisfaction and are highly commended by many of the leading physicians of this city. For convenience, a number of the most usual formulæ are prepared, and a box containing ten or a dozen minute vials, with these small wafers, will be found a very valuable addition to a physician's armamentarium.

Women as Physicians.

It is pleasant to see that the *British Medical Journal* publishes some hospital reports by "Miss Clarke, M.D.," and very good ones they are. The bigotry of the British Medical Association is sufficient to exclude women from its membership. But Mr. Ernest Hart, the editor of the journal of the Association, does not partake of this narrow spirit, and his wife is an extremely able and cultivated medical writer, often contributing to the *London Medical Record*, a monthly journal largely controlled by Mr. Hart.

Kant's Skull.

Professor Kupffer, of Königsburg, describes the skull of Kant, which was recently disinterred. Its capacity was 1715 centimeters. The sutures were remarkably perfect, well retained and regular. The skull is broad for its length and height. The right side of the cerebral portion and the left of the cerebellar portion were the most developed. The cavities of the eyes were unusually high. In general, it was a mixed type, as Kant himself was, his grandfather having been a Scotchman and his mother a South German.

Centenarians.

A woman is reported to have died in Strasburg, at the age of 102. Herr A. L. Dicksten, a "teacher of religion" in Heringen, celebrated his 107th birthday last month. He is said to still possess great freshness of intellect.

Items.

—"No kiss," he said, despondingly; "no kiss from my darling to-night?" "No," she said, emphatically, "no kiss. I hear that there is mumps in your family."—*The Sanitarian.*

—The Milwaukee (Wis.) *Sentinel* believes that it has discovered in that city a bogus medical college, which calls itself the Milwaukee College of Physicians and Surgeons, and has been issuing fraudulent diplomas.

—The College of Physicians and Surgeons, of Buffalo, has nullified the degree of M.D. recently conferred upon Wm. R. Crumb, of this city, it having been proven, upon examination, that the thesis upon which the degree was conferred was written by another person and handed to the faculty as original.

QUERIES AND REPLIES.

Cremation.

Dr. D. C. Leavenworth of New Haven, Conn., will thank readers to forward him copies of any essays, articles or papers on the subject of cremation.

Tribasic Phosphide of Silver.

MR. EDITOR.—Will your readers kindly furnish me, through your department of Queries and Replies, any experience they have had in the use of the tribasic phosphide of silver in nervous diseases? Respectfully,

Penna. C. C. H.

Portraits of Medical Men.

Dr. B. R. L., of Pa., asks: Will you be kind enough to inform me where engravings of eminent medical men can be purchased?

Ans.—In the *Biographical Dictionary of Physicians and Surgeons of the United States*, the steel engravings of fifty-two eminent medical men may be found. Price of the book $7.50. It is the best collection we know.

Dr S. W. J., of Texas, asks: Are chlorate and iodide of potassium incompatibles? if so why?

ED. REPORTER.—What is the date of the last edition of the *U. S. Dispensatory*, and does the last edition come fully up to the requirements of the day? Has it been superseded by the *National Dispensatory?*

Ala. Dr. S. S. G.

Ans.—The *U. S. Dispensatory* has been superseded by the *National*. The last edition of the former is a decade old.

Name Wanted. We received $5.00, in April, from Brunswick, P. O., no State given, and name undecipherable. Will the sender please write us.

Dr. G. W. C. of Tenn., asks: Will you please give, in your "Queries and Replies" column, the composition of "Simmon's Liver Regulator."

Ans.—We have seen no analysis of it. Perhaps some of our readers have.

Query.—What about the propriety of blistering an infant (six months old), making the blistered surface to cover the entire front, reaching from ensiform cartilage to the pubis; also blistered from nape of neck down spinal column, two and a half by four or five inches. And what about the propriety of painting such extensive blistered service with croton oil. Diagnosis *said* to be congestion of the brain and bowels. IKE.

Texas.

Ans—Propriety might be consulted by submitting a physician who did it to the same treatment, in order to impress upon him more sense the next time. It is simply barbarous ignorance.

MARRIAGE.

McANINCH—McDONALD.—On Thursday, May 19th, 1881, at the residence of the bride's parents, Butler County, Pa., by the Rev. S. P. Dillon, D. L. McAninch, M.D., of West Freedom, Pa., and Miss Ella McDonald.

DEATH.

LINDLEY.—At her residence, three o'clock P M., Friday, May 6th, 1881, Lou. C. Lindley, wife of Dr. Walter Lindley, of Los Angeles, and daughter of Rev. W. W. Puett, of the Indiana Methodist Episcopal Conference.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

CLINICAL VARIETIES AND TREATMENT OF PNEUMONIA.

Delivered at the Cochin Hospital,

BY M. BUCQUOY,

Prof. Agregé, of the Paris Faculty of Medicine.

Translated for the Medical and Surgical Reporter.

Gentlemen:—At a purely clinical point of view we may constitute several varieties of pneumonia, in taking as basis three categories of facts: 1st. The pathological anatomy. 2d. The etiology. 3d. The symptomatology.

(A.) Taking as basis the post-mortem conditions of the lung, two forms of pneumonia may be admitted; ordinary acute pneumonia, or lobar pneumonia, and lobular pneumonia, or broncho-pneumonia.

Lobar pneumonia is constituted by the presence of a fibrinous exudation in the pulmonary alveoli, filling them so accurately that an exact cast of the alveolus is often found in the expectorated matter; this condition induces a veritable hepatization of the lung.

This exudation sometimes extends into the last ramifications of the smaller bronchial tubules, very near the pulmonary alveoli; the exudation being produced either on the mucous membrane of these minute tubules, or belonging exclusively to the surface of the vesicles themselves.

It is to this form of pneumonia that the Germans have given the designation "croupal;" this is making a forced extension in the application of a term to which we have already assigned a more precise signification; it is much more logical to conserve for this form of pneumonia a name drawn from the post-mortem appearances, and to call it fibrinous pneumonia.

We have, again, catarrhal pneumonia (also called lobular, or broncho-pneumonia); this designation has been applied to it on account of the special conditions which induce it, conjointly with other affections of mucous surfaces. It is characterized by abundant secretion analogous to that observed in catarrh of all mucous surfaces; a muco-purulent liquid secretion, easily distinguished from the fibrinous mass of the first variety. Lobular pneumonia is limited to one or several lobules, never affecting an entire lobe or part of a lobe; the parts affected are more limited and more disseminated. It is called broncho-pneumonia, because it originates in an inflammation of the smaller bronchial tubes, propagated or extended to the pulmonary alveoli.

A distinction must be made between the broncho-pneumonia observed in young children and that of the adult. In children, broncho-pneumonia is not true pneumonia, it is the extension of catarrh to the pulmonary alveoli, but the inflammatory process has respected the parenchyma; it is a variety of pneumonia without inflammation of the parenchyma. In children who have succumbed, particularly during the first two years of life, the lungs may be perfectly distended with air; the vesicles have been filled with the exudation, whence simple atelectasis and congestion, preventing the access of air and inducing paralysis of the pulmonary vesicle, but nothing beyond this. You will very frequently meet with broncho-pneumonia in the adult; sometimes it is met with having the simple characteristics of pulmonary atelectasis, as in children; but there is, ordinarily, inflammation

of the parenchyma. It is a catarrhal affection of the respiratory passages, a generalized bronchitis, complicated with true, limited, fibrinous pneumonia. It must not be supposed that it is simple bronchitis, without inflammation of the parenchyma, as in children; there is always fibrinous pneumonia in the adult, small sections of the lung being affected; the expectoration is very abundant, the onset insidious and accompanied by more or less generalized bronchitis. This form has not the brusque onset of true lobar pneumonia; the general physical signs also are characteristic, and disappear promptly. It is, in a word, a variety of pneumonia of much less gravity than the first form, and can be treated with safety on the expectant plan.

Histologists admit other forms of pneumonia; according to them, the pulmonary tissue, the fibro-vascular framework of the alveoli, is intact in the two forms we have just examined, and which they regard as examples of intra-vesicular pneumonia, the alveolar parietes not being affected; but they admit, besides, an interstitial pneumonia.

This form being rare in practice, I will not consider it in this study, and with greater reason, since I cannot admit that in the hepatization of true lobar pneumonia the pulmonary parenchyma is intact; without doubt, resolution of the inflammation takes place and the patient is saved; but that does not prove that there has not been inflammatory hyperæmia; the localization of the process in the alveolus alone is entirely theoretic.

I admit, however, that there is reason to insist on a more marked localization of the inflammatory process in the parenchyma in interstitial pneumonia, particularly in the chronic forms of the disease.

Besides these two forms, in practice we meet with hypostatic pneumonia (Piorry), which is the result of prolonged congestion, under the influence of stasis of liquids, or through the horizontal position in chronic diseases; but this is not veritable pneumonia; congestion must not be confounded with inflammation.

Nevertheless, in serious cases of typhoid fever, for instance, sibilant râles are sometimes found with veritable souffle and undoubted signs of pneumonia; there is no true hepatization, no fibrinous exudation, but scattered in the congested tissue, limited masses (noyaux circonscrits) are found, seemingly in a hepatized condition, resembling muscular tissue; it is a condensed tissue, from which a serous liquid exudes on pressure. It is what was formerly called carnification of the lung, and what M. Charcot has recently described under the designation, "carnization."

In such a case there is more than atelectatis; there exists veritable inflammation of the pulmonary tissue (trame pulmonaire).

(B.) Symptomatology again furnishes us with a second category of varieties of pneumonia. In the classic authors are found the description of the two forms, bilious and typhoid. The bilious form is much spoken of and little known; after the summer heats a few examples of true pneumonia complicated with the bilious state of ordinary gastro-hepatic catarrh (embarras gastrique) are met with. The typhoid form is much more frequent. This variety of pneumonia appears sometimes with an adynamic character, sometimes with nervous or ataxic phenomena. Typhoid forms of pneumonia have considerable tendency to suppuration. I will not delay on the consideration of latent pneumonia, observed, ordinarily, in aged persons, and of which the signs are very obscure.

Such are the forms adopted by the classic authors, but it is truly remarkable that they have not devoted more attention to the catarrhal form; this variety of pneumonia is frequently met with, being brought on by a chill under certain conditions of the atmosphere, etc. It is characterized by its onset, less brusque than in ordinary pneumonia, and preceded by symptoms of influenza, a slight stitch in the side, abundant expectoration, less marked fever and rapid resolution; isolated portions of the lung tissue (foyers circonscrits) are affected. Notwithstanding its somewhat alarming commencement this variety of pneumonia generally ends in resolution on the fourth or fifth day.

Another form merits attention. I speak of intermittent pneumonia, of which I observed a case at the outset of my medical studies, and another at the Hôtel Dieu, in a patient just returned from Algeria.

Sulphate of quinine gives good results in this affection, of which some authors have, without sufficient grounds, denied the existence. It presents itself with all the characters of true pneumonia, then suddenly disappears for a day or two, and then the symptoms reappear as intense as during the first days.

(C.) The peculiarities we have just observed, as regards intermittence and the influence of existing medical conditions, already show that etiology has its part in establishing the diverse varieties of pneumonia. The importance of causation is particularly remarkable in those dis-

eases where pneumonia supervenes as a complication.

Thus the existence of a rheumatismal form of pneumonia has been admitted, in which it is affirmed the pulmonary phenomena disappear as rapidly as the articular phenomena, and are dissipated in a very short time.

Such cases are rare. This rheumatismal form of pneumonia, presenting the characters of acute fibrinous pneumonia, like broncho-pneumonia, affects a large part of the lung, but has no tendency to pass to the chronic state. Puerperal pneumonia presents no peculiar characteristics; nor do certain secondary pneumonias, consecutive, for instance, to typhoid fever, the eruptive fevers, or to a traumatism, as the wound produced by a sword thrust; these punctures of the lung heal, ordinarily, with the greatest facility.

Lack of time prevents any extended consideration of the different varieties of pneumonia; nevertheless, I do not wish to conclude without saying a word concerning the localizations of pneumonia.

You know that there has been much discussion regarding pneumonia of the apex of the lung. Andral considered such cases of greater gravity than others. Briquet observed no difference in the mortality. Grisolle concluded, on the contrary, that pneumonia of the apex was of greater gravity than other varieties.

Is it because the pulmonary lesion is nearer the brain? Certainly not; and yet the fact is proven that these varieties of pneumonia are more frequently accompanied by adynamia or ataxic phenomena; this is what gives them a special character of gravity.

Prognosis should, in general, be guarded, in pneumonia, when localized in other than the usual situations; pneumonias of the apex terminate favorably when the entire thickness of the lung is not affected; if you find the signs of pneumonia equally marked under the clavicle and in the supra spinous fossa, the prognosis is bad; of the entire number of cases of these pneumonias "which traverse," I have observed but one case where the termination was favorable, and in this case the inflammation seemed to be simply diffused over the surface, after the manner of erysipelas.

As regards pleuro-pneumonia, it is an ordinary complication of acute pneumonia; the pleuritis is explained by the close proximity with the inflamed lung, and particularly by the intimate correlation of the circulation of the two organs. The pleuritis gives rise to the stitch in the side, but adds little to the gravity of the pneumonia, and terminates ordinarily with it. Nevertheless, in certain cases, the effusion into the pleura remains for a time, but is always of great benignity, and never requires thoracentesis. Cases are observed, however, where inflammation of the pleura causes pulmonary inflammation and carnification of the lung under the points where the pleura is inflamed; in such a case, a layer of congested and carnified lung tissue, four or five centimeters in depth, is found under the inflamed pleura.

Treatment.—To-day we have abandoned the systematic practice of any one treatment of pneumonia to the exclusion of the others; we should consider if we are in the right path. To establish this, we shall be obliged to go over all the statistics and determine, for instance, if the mortality in pneumonia treated by general bleeding is less than in cases where tartar emetic has been employed. I believe that this would be an objectionable method, which would lead to erroneous conclusions.

In order to make statistics it would be necessary to collect comparable cases; for, to count in block all the cases of pneumonia observed in a hospital, is completely irrational; certain cases have been treated from the onset, others entered when the inflammatory process was on the decline; some of the cases existed in young subjects, others in aged subjects, etc.

It is necessary to establish distinct categories. As proof, it will suffice to cite the following fact: I found, recently, among my notes, a statistical table of all cases of pneumonia treated in my service during the year 1875; a table compiled with care by my late interne, Mounoir; out of 65 cases of acute pneumonia there was a favorable termination in 54 cases, and death ensued in 11 cases; that is 20 per cent. of mortality; not a very favorable result. Or, if we reconsider this series of patients, we find that 25 were over fifty years of age; of this number, 15 recovered and 10 died; that is 40 per cent. of mortality. Of the 40 other patients of less than fifty years of age, 39 recovered and but 1 died, and he was a subject given to drink; the rate of mortality descends for these 40 patients, to 2.5 per cent.

It might be said, if the cases were considered all together, that with a mortality of forty per cent. my treatment must have been objectionable; while taking into consideration that our patients in this hospital are often aged men, worn out by all sorts of privations, and coming to the hospital but to die, the success of our method of treatment will be recognized.

No one exclusive method of treatment should be adopted for pneumonia, no more than for any other malady. The treatment should vary with the indications which present themselves; pneumonia is not a morbid entity to be combated regardless of the patient; on the contrary, it is necessary to treat the patient, and not the malady. It is, then, a question of opportunity; it remains to determine under what circumstances we should utilize each of the diverse forms of treatment recommended in pneumonia.

And in the first place, can the expectant plan be admitted; within what limits is it possible for a pneumonia, abandoned to itself, to have a favorable ending? A few years since such a plan of treatment would have seemed unjustifiable, and even criminal; nevertheless, every day we observe cases, even without desiring it, where pneumonia has a favorable ending without any treatment whatever; thus, a poor laborer is taken down with pneumonia; he remains in bed because he finds it impossible to work; he has no medical attendance, and finally, on the fifth or sixth day, he is brought to the hospital with a pneumonia which has followed a satisfactory course; there is no fever, the patient is almost convalescent, and we have but to assist at a spontaneous cure. It has been often thought that such cases of pneumonia had a greater tendency to become chronic, and that resolution of the inflammation was more tardy, but such is by no means the case; their course is as regular as in cases which have undergone the best treatment. And note well that I speak of patients who follow the expectant plan, involuntarily, under the most deplorable hygienic conditions; the results are much more favorable with patients in comfortable circumstances, living under the best conditions, hygienic and otherwise. In such patients expectation is not inaction; the patient is perfectly at rest in bed, with the diet carefully regulated, and has the thousand little cares bestowed on a patient in a febrile disease.

This is an entire plan of treatment, although no drug be administered, and we do not quit the expectant plan when we apply wet cups, to combat the stitch in the side, or when a potion is prescribed, to calm the paroxysms of cough.

The expectant plan may then be followed in all cases where the natural tendency of the malady is to recovery; that is in adults and in children over two years of age or thereabouts; with the condition that they be not already debilitated by any cause, and that they present no trace of any other anterior disease; the inflammation again should be limited and have no tendency to diffusion.

Bleeding was formerly carried to such an extent that the present generation of physicians abstain completely from this method of treatment. The reaction has led too far; we cannot admit that Chomel, Andral, Louis, and Grissolle were always mistaken when they upheld this practice of bleeding; and although they were obliged to combat the too exclusive practice of Bouillaud, were compelled to admit that bleeding was often of benefit, and followed the practice themselves in pneumonia. It has been said that patients cannot bear bleeding now as formerly. We are not a collection of feeble, anæmic subjects, as has been too often repeated, and we would bear bleeding as well as did patients twenty-five years ago.

In young subjects, in cases of pneumonia with widely diffused hepatization and intense reaction, bleeding is of real utility at the onset of the malady. In our hospitals you do not often observe bleeding, but it is because the patients arrive often towards the fifth day, when hepatization has already taken place and the inflammation has become limited; when consequently, there is nothing more to prevent; the dyspnœa and fever might be diminished, but with the risk of enfeebling the patient at a period when his strength should be guarded in order to arrive at prompt resolution.

In private practice the occasion for bleeding occurs more frequently, for the physician is called at the onset of the malady; and it is certain there is too much hesitation in bleeding in such cases.

I have often regretted, on the third day of a pneumonia, not to have attacked it on the first day by general bleeding, which would have diminished the inflammation and prevented its extension.

When pneumonia is accompanied by intense pain in the side, considerable dyspnœa and high fever, when, in other words, the inflammation is intense, bleeding will prove beneficial.

Abstracting 400 or 500 grams of blood will have considerable local effect on the inflamed lung, will relieve the patient, render the pulse stronger, and cause a reduction in the temperature.

As regards local abstraction of blood there is much less scruple: you see wet cups applied every day. In country practice, leeches should not be forgotten, to diminish cough and relieve the stitch in the side.

The contra-stimulant medication, combined with bleeding, constitutes the French method of treatment; it was instituted by Laënnec, and

Grisolle put it in practice up to his death. Tartar emetic seems to be the remedy par excellence, in pneumonia; it causes, first, vomiting; then tolerance becomes established, but a feeling of nausea remains, the pulse becoming stronger and the temperature falling. But the doses have to be repeated, and these results are obtained only when the toxic effects of the drug are arrived at. I fear this state of artificial adynamia. I am willing to administer tartar emetic, after the method of Rasori, but as soon as tolerance becomes established, I arrest the treatment and seek to combat the effects of the adynamia.

I have seen Aran treat pneumonia by veratria, giving 25 to 35 centigrams (4 to 5 grains) per diem, in pills containing 5 centigrams ($\frac{3}{4}$ of a grain each); he thus induced profound adynamia and a state of great debility, which I should by no means desire to produce. It is not, in effect, demonstrated that by such treatment the duration of pneumonia is diminished, or its ravages considerably attenuated. If the case seems to be of too much gravity to follow the expectant plan, and if an extensive portion of the lung is in the hepatized state, I prescribe 30 centigrams ($4\frac{1}{2}$ grains) of tartar emetic, in a julep, one spoonful to be taken each hour, so that after eight hours the nauseating and emetic effects of the drug have been obtained, and tolerance becomes established. This suffices to lower the pulse and the temperature. The next day I do not continue the use of tartar emetic, and if the patient be at all feeble, I stimulate by an alcoholic preparation (brandy mixture, etc.). If the patient does not seem prostrated, and if the malady follows its normal course, I return to simple expectoration.

I make use, sometimes, of tincture of digitalis, particularly in catarrhal varieties of pneumonia. As regards veratria, it is an atrocious medicament, that I completely reject. Medication by tonics and alcohol is much more frequently indicated, particularly in debilitated subjects, who stand in need of stimulation, in order that complete resolution of the inflammation may be obtained. It is thus that alcohol should be employed; it is not a specific remedy in pneumonia, but it places the patient in proper condition, that resolution may be brought about. You all know the success which has attended this medication in England. It is useful in pneumonia attacking drunkards; for these individuals, depressed and enfeebled, alcohol stimulates the nervous system and continues a state of excitation to which they have been accustomed; it places the patient in his usual condition of health and permits him to traverse fortunately the course of the malady.

I will not devote a lengthened consideration to the indications for emetics and purgatives; they have an antipyretic action, at the same time lessening the pulmonary inflammation (défluxionnent le poumon). The indications for the use of emetics will be found in benign forms of pneumonia, in catarrhal pneumonia with bronchitis, etc.

Patients are purged too frequently; this effect is produced by tartar emetic, but is not sought; in general it is better to avoid the use of purgatives. Blisters are also too frequently employed; it is a deplorable method. Generally, to-day, the special indications of the particular case are not sufficiently considered.

Blisters are applied at the onset of the malady, and give little relief to the patient; it would be much better at this period to apply wet cups; blisters should not be applied until later, if the resolution of the inflammation is tardy; if they are applied too soon, they cause elevation of the temperature and exaggeration of the febrile state. It is at the terminal period of the malady that blisters should be applied. The alkalies and iodide of potash may be employed at the same time, if the inflammation shows any tendency to pass into the chronic state, and enters but slowly into the period of resolution.

Communications.

RAPID AND EASY CURE OF A CASE OF MORPHINE HABIT OF TWELVE YEARS' STANDING. AMOUNT USED SIXTEEN GRAINS PER DAY.

BY H. H. KANE, M.D.,
Of New York City.

The number of morphine habitués is at the present day so largely on the increase, that any plan of treatment offering a rapid cure, unattended by marked suffering, is sure to be welcomed by the profession, the more so, as many of the victims to the habit are physicians. For the past year I have been taking these patients into my own house, where the facilities for careful observation and prompt treatment are greater than when the sufferer is in his own house, or at a hotel or boarding house, near by. I have thus been enabled to carefully note and record the cases I have treated, and to compare accurately the merits of one plan of treatment with another. My plan is that of rapid reduction, which has all the advantages and none of the drawbacks and

dangers of the German method. Patients leave me as fully and permanently cured, in as short a time and with less suffering than when treated by Levenstein's plan, of sudden deprivation.

By it, moreover, patients so much debilitated from the long continued use of morphia, or from coexisting organic disease, whom it would be wholly impossible to treat safely by the plan of sudden deprivation, can be taken in hand at once with a marked prospect of success. One such patient, a physician, with decided spinal and cerebral sclerosis, ataxia and frequent epileptiform convulsions, and very much emaciated and debilitated, is now under my care. He is two-thirds through the reduction, and has suffered from nothing save slight nausea. He says that, when "broken" before, some two years ago, he suffered markedly, especially with pains in the limbs, angina pectoris, palpitation, vomiting and purging, restlessness, and insomnia.

A case that has but recently passed from under my care may serve as a good illustration of some points in the treatment pursued.

C. P., Pennsylvania, a clerk, aged forty-two years, a widower, no family history of alcoholism, insanity, drug addiction, marked nervous disease, or syphilis.

In June, 1871, while dispensing some one-eighth of a grain of sulphate pills, he put one in his mouth, swallowed and forgot it, until going home to dinner, when he noticed that, whereas on former occasions he had been worn out and hardly able to drag one leg after the other, now his step was light and springy, and his appetite excellent. He was at a loss to account for this decided change, but finally thought of the morphia pill he had taken, and, as he had taken nothing else, supposed that it must have been that. Taking his vacation a few days later, he took one hundred of these pills with him, and swallowed one every morning. On his return to Chicago he took no more, the carrying out of his resolve being attended with pains in the limbs, restlessness, dullness, and insomnia.

In the fall of 1871 he lost all his property. So worried and prostrated was he by this that he could not sleep, and on the advice of a physician who was in his store one day, he again took a $\frac{1}{8}$ gr. pill. Took one pill twice a day for three months. Then stopped their use at once, being afraid of the consequences. He, however, began to use the drug again in the winter of 1871–72, and continued its use for four years, after a time reaching the daily quantity of sixteen grains. At the end of this time he found his appetite good, bowels somewhat constipated, sexual appetite gone, urine variable in quantity from day to day, temper extremely irritable, eyesight unaffected, no chills or fever, no delirium, but considerable gastritis, with attacks of vertigo, and occasionally syncope. Finally his stomach rebelled at any preparation of opium or its alkaloids, and, making a virtue of necessity, he stopped its use at once. He then suffered from chills, high fever, intense nausea, restlessness that was almost constant, and he finally sank into a low typhoid condition attended with some delirium. The pains in the limbs were constant and very severe. On the fifth day of this struggle he was given two one-eighth grain morphia powders which somewhat relieved him. Did not get about until September, 1875. Did without morphia until January 1, 1876, when, from inadvertently taking some laudanum he relapsed into the old habit, and was soon taking one drachm of the sulphate of morphia each week. In September, 1877, he was again broken of the habit, but relapsed in June, 1880, since which time he has been taking two drachms each week. Find the patient, on admission, a tall, sallow complexioned, weak looking man, apparently easily tired. Face of reddish hue, skin coarse, eyes light blue, hair light brown, slightly deaf. Is using two drachms morphia per week. Pulse about 76. Complains of nothing but loss of sexual appetite and a slight cough, which is found to be due to intense venous congestion of the whole pharynx and larynx. Urine slightly albuminous, and containing a few medium-sized hyaline and light granular casts. No sugar. Specific gravity, 1.019. Reaction acid.

Allowed him to rest for one night, and in the morning gave him—

℞.	Morphiæ sulphatis,	gr. vj
	Quiniæ sulphatis,	gr. viij.

Passed a perfectly comfortable day and night, although somewhat restless toward morning. Sneezed twice during the forenoon.

Second day. Gave

℞.	Morphiæ sulphatis,	gr. iij
	Quiniæ sulphatis,	gr. x.

Some slight sneezing, appetite good. Went out walking. Then ordered

℞.	Sodii bromid.,	gr. xv
	Potass. bromid.,	gr. x
	Tr. digitalis,	gtt. j
	Tr. cinchonæ comp.,	℥j
	Pulv. sacch. alb.,	gr. x.

Sig.—Every three hours.

Also

℞.	Auri et sodii chlorid.,	gr. $\frac{1}{16}$
	Tr. acteæ racemosæ,	
	Tr. cinchonæ comp.,	āā ℥ss.

Sig.—Every three hours.

Third day. Restless. Did not sleep well, although given 20 grains of chloral in two doses. Slight pains in limbs. Slight nausea. Gave one grain of morphine and ten grains of quinine. Pains in limbs wholly relieved by general faradization. Sinking sensation at pit of stomach yielded readily to compound tincture of cinchona and hot water. Took beef tea with relish. Stomach somewhat distressed after it. Pulse 42. Faradization. Stopped bromide mixture.

Fourth day. Slept some four hours. Feeling weak. Continued medicines, with the exception of the bromides. Gave one-half of a grain of morphine and ten grains of quinine. The bowels not having moved, gave

℞. Mass. hydrarg.,
Ext. colocynth. comp., āā gr. iv,

to be followed in six hours by a Seidlitz powder. Owing to lightness of all symptoms, began to suspect the patient was getting some morphine. This, however, was not the case. Gave whisky, but found that it caused nausea.

Fifth day. Did not sleep well until a hypodermic of one sixteenth of a grain of morphia was given. Weak, but sat up to have bed made. For the nausea gave ten grains of bismuth, two grains of the oxalate of cerium, and two drops of hydrocyanic acid in mucilage acacia, every hour, until relieved. Small dysenteric discharges of a brownish-green color. Ordered tincture of hyoscyamus in two-drachm doses, to be repeated in two hours, if necessary, as a sleeping mixture.

Sixth day. Slept very well. Somewhat troubled with dysenteric symptoms. Stopped all medicine but the digitalis and whisky; the former in two-drop doses, every three hours. Electricity at night.

Seventh day. Slept well, with exception of occasional awakening; at four o'clock bowels began to move and kept him awake the rest of the night. Next day somewhat prostrated. Took in addition to beef tea, which he has been using, some poached eggs and a cup of tea. The distress after each was measurably relieved by—

℞. Pulv. pepsine (Hawley's) gr. x
Tr. nucis vomicæ, gtt. xx
Tr. hyoscyami, gtt. xxx.
Sig.—At a dose.

From this time on, by use of above mixture, digitalis, hot baths (106°–110° Fah.) followed by general and local faradization, patient improved in strength, spirits, appetite, and sleep. On the twelfth day, returning sexual power was indicated by nocturnal emissions. Went out into the open air, in charge of a nurse, and in two weeks from date of entering the house was discharged, with a fair appetite, power to sleep without medicine, and urine free from all morbid deposit. The pulse rose on the eighth day to sixty-four, and gradually came up to one hundred, at which point it was beating when he left, it being regular and healthy as regards tension frequency. His pulse in health was always high, and would occasionally intermit. From here he went to a country town in this State, to still further recuperate. He seems to have absolutely no craving for morphia.

This case is peculiar in many respects. In the first place, the contrast between the method of cure by sudden deprivation and by rapid reduction is marked, and greatly in favor of the latter. It is the more noticeable as the two methods had been tried on the same patient, that by rapid reduction at a time when it would be naturally supposed that the effort at cure would be attended by the most suffering. As is seen, the characteristic pain in the limbs, nausea and vomiting, collapse, dyspnœa, restlessness, and delirious excitement, were either entirely absent, or of so slight a nature as to require but limited special treatment. Baths were not given until several days after the use of morphia had been entirely stopped. Heretofore, baths have been the most important feature of treatment in these cases. Stimulants were used but for three days and were then objected to by the patient, as they distressed the stomach. Marked relief to the pains in the limbs and sinking at the stomach was afforded by general and local faradization.

It has been said that it was suspected, from the lightness of the symptoms, that morphia was being taken on the sly. Being well acquainted with the cunning of these patients, I caused the closest search to be made and watch to be kept, and this resulted in certain disproval of the patient's taking the drug, showing that the usual distressing reflex troubles incident to deprivation of the drug* were being successfully combated by the medicines used. The rapidity of recuperation displayed by this patient is shown in the fact that on the eighth day of treatment and the fourth after the last dose of morphia had been taken, the patient walked out, rode to the ferry in the street cars and crossed to the Jersey side, coming back the same way. He was then able to mount two flights of stairs to his room.

I now exhibit the chloride of gold and sodium in the form of Fuller's tablets, which are easier to give and distress the stomach less than fluid

* "Drugs that Enslave." H. H. Kane, Philadelphia, 1881.

medicine. I have the machine and find the tablets easy to make and pleasant to take.

In conclusion, it may be said that the curative treatment of these miserable patients is now easy, satisfactory and rapid, and it is time that members of the regular profession, knowing these facts, should endeavor to aid those who are especially studying and treating such cases, by placing them under their care rather than let them drift from the hands of one quack to those of another, to be fleeced and physically injured each time.

The patient will be in Philadelphia in a few weeks, and should any physician desire to see him and verify the statements here made, I will gladly send them his address.

191 *West 10th street, N. Y.*

INCONTINENCE OF URINE IN BOYS.

BY JOHN MORRIS, M.D.,
Of Baltimore, Md.

Read before the Baltimore Medical Association, April 25th, 1881.

The subject to which I shall call your attention for a brief period, to-night, is one of a practical character, and well worthy, I think, of our consideration. It was suggested to me recently by a philanthropic gentleman of the city, connected with most of our public charities. In a visit with him to some of our reformatories, I was surprised to find, on inquiry, that one boy in every twenty suffered from incontinence of urine. At the reformatory for colored boys, in Prince George's County, the ratio is still greater. On further inquiry, too, I discovered that this serious trouble exists, almost to the same extent, in many of our boarding schools. This is certainly a very unpleasant, if not a startling condition of things, and has been entirely overlooked heretofore, by those having charge of our reformatory institutions. It may be possible that the disease was deemed intractable, and consequently, received but little notice. Incontinence of urine in children does not, I think, prevail to so great an extent in private practice. If it does, it is a serious reproach to parents and to our profession—a reproach which should at once be wiped out, by proper and earnest efforts in the future. It is a surprise that a subject of so grave importance as incontinence of urine should not have received greater consideration from the profession. Our text books afford us very little information in regard to it, and every medical man, when called to treat a case, has to rely almost solely on his own experience. I shall, in my address to-night, confine myself to nocturnal enuresis in children, because we are more frequently called on to treat this disease than the bladder troubles of old people, which are of an entirely different character. I have said that our text books afford us very little information in regard to this matter, but during the past few years a number of articles have appeared in the journals, containing suggestions of more or less value on this subject. Before the appearance of these articles this disease had been treated almost at random, and nothing of a scientific character was suggested for its relief. It was looked on as one of the *opprobria medicorum*, and its poor victims were left to the mercy of the merest empiricism.

Incontinence of urine in old people is frequently an evidence of some severe nervous lesion, but it is not so in the young. In the latter it is a curable disease, and exists almost always independently of brain or spinal trouble. It may result from a number of causes, the most frequent of which are intestinal irritation, acidity of urine, worms, defective nutrition, feebleness of constitution, and, possibly, teething. A very frequent cause, too, is a nervous temperament, or diathesis, independent of any organic disease; but the most frequent cause of all, in my judgment, is a condition of the bladder, or rather of the sphincter, brought on in early youth, through the slovenliness and inattention of mothers and nurses. They feed the child with improper food, and suffer the bladder to become distended before putting it to bed. No attention is paid, even during the day, to see that the urine is voided at proper intervals. The consequences of this inattention are daily recognized by medical men on entering dwellings and rooms occupied by these poor, forlorn children. To make it plainer, it is enough to say that the odor of these apartments is not that of "Araby the blest."

In the treatment of the disease it is necessary for us to ascertain its origin. The history of the child, and its habits from birth, as well as the family history, should be inquired into. The urine should be tested for acidity, and the bladder and rectum, if needs be, examined. Atony of the bladder might, by causing over distention, give rise to it, or undue irritability might prove sufficient to overcome the resistance of the sphincter. If incontinence be due solely to acidity of the urine, it is easily cured. The administration of a simple alkali in combination with benzoic acid is all that is necessary. A solution of benzoate of soda, combined with a very small quantity of belladonna, will be found very useful in this condition. This form of the disease is owing to per-

verted secondary assimilation. If the disorder is caused by worms, some anthelmintic remedies will be required; but worms in this affection, as in many others, are simply a *bugbear*. Intestinal irritation, no matter from what cause, must be met by proper agents; defective nutrition, by the use of cod-liver oil, iron, and a judicious general regimen, embracing the cold bath, fresh air, calisthenics, etc.

The form of the disease most amenable to treatment, and which, as I said before, is very common, is the purely nervous form. It is most frequently met with in boys and girls of a lymphatic or scrofulous temperament. They lose the coördinating power, at first, from the will not being called on and properly exerted, and this is afterwards kept up by habit. In these cases the syrup of the iodide of iron and the cold sitz bath act as a specific, particularly if aided by moral means. Large doses of the iodide of iron must be given to the big and strong boys in public reformatories. The reason that syrup of the iodide of iron is preferable, in cases of children, to other preparations of iron is, it is easily decomposed in the stomach. The iodine is set free, as Jacobi states, and acts as an anti fermentative in the many cases of disturbed gastric digestion occurring, even in normal children whose circulation has been disturbed, or whose gastric secretions are certainly below their normal amount, in consequence of a deficient supply of blood. If nocturnal enuresis exists with daily incontinence, belladonna may be given with the iron at bedtime. I can speak with great confidence of these last two remedies. I have given them a fair trial, and in every instance, save one, have they proved beneficial; indeed, in my judgment, they are the only drugs which have any real value in this disease. Strychnia has no specific powers, and I much doubt if a single cure has been effected by it. In cases of atony, or paralysis of the bladder, I believe it might, in combination with syrup iodidi ferri, prove highly efficacious. In abnormal irritation of the bladder, belladonna is our best remedy, and far preferable to conium or henbane; the bromide of potassium has been recommended, but I think it almost useless. Tincture of cantharides has no virtue whatever, at least I have obtained no good results from its administration.

In the purely nervous form of the disease that I have heretofore described, the condition of the urine is very singular. It is voided in large quantities; it is limpid, almost colorless, and lacks the normal ingredients. Hysterical patients, as you all know, pass enormous quantities of limpid urine, and from precisely the same cause. The diet of the little patients suffering from this particular kind of enuresis is an important matter. From their family history, peculiar temperament, and other causes, they are apt to be over indulged, and the loathsome penalty they pay is oftentimes but a retribution of the gods.

In mechanical means I have no confidence whatever. I have tried Sir Dominick Corrigan's remedy, the application of collodion over the meatus, but obtained no good results. As I left it to the patients themselves to make the application, it may be possible that it was ineffectively done, or perhaps the collodion itself was defective in quality. I think it possible Sir Dominick's suggestion may prove useful in other hands and under better conditions, and I shall certainly recommend its trial in the public institutions I have referred to. It is, at least, the only one of the mechanical remedies that possesses the slightest trace of merit. Of course, if incontinence of urine can possibly be superinduced by congenital phimosis, an operation is necessary. I invariably examine the prepuces of my patients, with a view to the discovery of any local trouble. Trousseau's truss, the passage of a catheter, the injection of warm water, as proposed by Dr. Braxton Hicks, Pluvier's pads, applying a nail to the back, a circular band around the pelvis, etc., etc., are not only useless, but injurious.

As to the kind of moral means to employ, I have very little to suggest; the judgment of the practitioner must be exercised in each particular case. It is only in cases of a purely nervous character that the old mode of treatment, by whippings and scoffing, has any value, if it has value at all. Though the nervous supply of the bladder is derived from various sources, and though the sympathetic is the controlling influence, there is enough of voluntary power derived from the cerebro-spinal system to play an important part in our treatment. It is this power that is evoked and brought into action by the moral means before indicated. Hydrate of chloral was suggested some years ago, to be given in ten-grain doses, at bedtime. It was said to act very kindly, by giving rest to the bladder and sphincter, and thus enabling them to regain their normal tone. I have given it a trial, but with no satisfactory result. I have no doubt that it might prove useful in cases of spasm of the bladder. I shall recommend its trial on a larger scale, to the gentlemen having charge of public institutions and boarding schools, in a lay pamphlet which it is my purpose to prepare at an early day, for their use. The preparation of

this pamphlet has been suggested to me by the philanthropic gentleman referred to in the beginning of this paper.

I am convinced that a fair trial could be given to all the remedies that have been suggested for incontinence of urine, if undertaken properly and systematically, in our large institutions for the reformation and education of boys. I am also convinced that if the medical man had under his own immediate charge all the cases he is called to treat, so that he might see that proper food was given, tea and coffee, or other slush avoided; hard beds and light bed clothing used; the urine voided at certain regular hours, particularly before retiring, in addition to constitutional remedies, a far greater number of cures would be effected. As it is, he has to rely solely on the few means that I have briefly suggested.

In conclusion, let me say that I have no confidence in any treatment that is not constitutional. Enuresis is always a sign of mental or physical weakness; the strong in mind and body are never its victims. Let our efforts, then, be directed to the building up of the physical nature of our patients, so that they may enjoy that greatest of all boons, a sound mind in a sound body.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

CLINIC OF PROF. D. HAYES AGNEW, M.D.,
May 14, 1881.

Reported by Guy Hinsdale, M.D.

Case I.—Trauma ic Tetanus.

This patient, two weeks ago, accidentally fell from a derrick, sustaining a compound fracture of the radius and a dislocation of the ulna. There being an external wound, it was a compound dislocation. He is forty-five years of age, and had been in excellent health until the accident. He had been doing well until five days ago, when he complained of some rigidity about the jaws. This increased, not by a regular progress, but it would at times lessen and then again increase. As I place my finger over the masseter I find it tense and hard. It is as stiff as a board. Over the temporal region there is extreme tension of the fascia, a continuous, violent spasm of the temporal muscles. He is incapable of separating his jaws.

This is trismus, or rather tetanus, for it extends beyond the limits of trismus; the muscles of the abdomen are tense and board like. The muscles of the chest are tense, also, but not to such a degree as was the case one or two days ago.

This is traumatic tetanus. We have two varieties of tetanus; first, the idiopathic, a rare form; second, the traumatic, which is by no means uncommon. This latter form may arise after any surgical injury, especially in the extremities, as, for instance, the toes and hands. Any accidental or designed wound may provoke tetanus; even a draught of cold air may bring it on. No ulcer or wound of any kind should be exposed to wind or cold. I recall two cases in point. One was a lacerated wound of the hand. The skin and subcutaneous fascia had been torn, but the patient was almost well and the wound had nearly cicatrized. While riding in a horse-car he exposed his hand to the wind, and on going home he soon began to experience some peculiar sensations, namely, muscular rigidity, not only of the jaws, but of the whole body, from the crown of his head to the soles of his feet. He became perfectly stiff and could be rolled about and turned over in bed, like a log.

Tetanus may follow any injury accompanied by laceration of the nerves, or one in which a nerve may have been accidentally included in a ligature.

Besides the other divisions that have been made, we have tetanus acute and chronic. The acute form runs its course with great rapidity, and is almost invariably fatal. A case of this kind, admitted to the house a few days ago, died twenty-four hours after admission. If the patient survive the tenth or twelfth day there is a fair prospect of recovery.

This man before you is better, and I think we can give a favorable prognosis. He swallows very well, but has still a little difficulty in speaking.

In the severe cases the jaws are locked; there is great difficulty in swallowing, and the water, or saliva, is sometimes violently forced out between the teeth. Owing to these phenomena, tetanus has been confounded with hydrophobia.

When the muscles of the back become violently contracted and the body rests on the occiput and heels, the disease is designated by the term opisthotonos; when the muscles in the front of the body are thrown into violent contraction, the condition is called emprosthotonos. When the muscles of one side are affected, and the patient is curved laterally, we have what is called pleurothotonos.

We know nothing of the pathology of this disease. By some authors the lesion has been located in the gray portion of the spinal cord, but nothing has been established positively, the post-mortem changes being, probably, of a secondary nature.

The treatment is far more important, however. I will not undertake to enumerate the various medicines that have been used in this disease. In the commencement of the attack I directed the administration of a brisk cathartic, clearing out the whole intestinal tract, followed by the use of chloral, which seems to have acted favorably; fifteen to twenty grains are given every two or three hours, according to the effect; in addition, one-fourth of a grain of morphia, hypodermically, is given every fourth or fifth hour.

There is, however, something else in the treatment quite as important as drugs, and that is nourishment, the frequent exhibition of nutritious articles of food. Stimulants should be liberally used, in the form of milk-punch. We endeavor to sustain the patient until the disease eliminates

itself. This man has taken, each day, sixty grains of chloral hydrate. It is not a large amount, and the treatment is having a happy effect. We will continue this, believing that the patient is going to recover.

Case 2.—Anchylosed Elbow Joint.

This young girl comes to us with a difficulty at the elbow. It is the result of a fall received five months ago. She was bruised at the posterior part of the arm, the force of the blow falling chiefly on the olecranon; the effect has been to leave her with a stiff arm. The injury has been a severe one, not simply affecting the skin and the superficial connective tissue, but it has involved the articulation. When I attempt to make flexion and extension, I find the joint immovable.

Affections of this kind are common at the elbow and knee joint, less frequent at the ankle. The ginglymoid, or hinge-joints, are more commonly anchylosed than the ball and socket joints; the structure of the former is more complex than that of the latter.

We need to exercise the greatest care in cases of this kind. Nothing definite is known of the patient's history; it is evidently one of those cases that we see arising from neglect. The proper course after the injury would have been to have put the arm absolutely at rest, using an angular splint and making an application of lead water and laudanum. Over the swollen surface of the joint the application of a few leeches would have had a beneficial effect. In from four to six days the inflammation would have subsided, and the swelling would have gradually disappeared, and then, passive motion being employed, all the effects of the inflammation would have faded away, leaving the joint uninjured.

After such an injury an effusion of a certain amount of lymph takes place. It may have its origin inside, from the synovial membrane, or the ligaments may be matted together from without. As a consequence of this inflamed state of the joint, we have rigidity.

There are two kinds of anchylosis, false and true. In false anchylosis there is no bony matter present, but a mere exudate, more or less organized, something which interferes with the proper motion of the joint; but in true anchylosis there is osseous matter covering the articulating surfaces, and it is impossible for this to undergo absorption.

The forcible breaking up of the adhesions, unless passive motion is subsequently kept up, does no good; the patient is left with a joint as stiff as before. In many instances we accomplish more if content to use a small amount of motion, the same repeated often.

On making pronation and supination I feel the adhesions breaking away. You see, we get very good movement. Be careful, in doing this, that the arm is not broken. Place it on a table and make slow movements backward and forward. The joint now moves freely, and all its motions are easily performed. There is, however, some grating of the articulation, the delicate surfaces of which are covered with a product resembling shreds of omentum or frost-work.

We will now wrap up the joint in cloths saturated with lead-water and laudanum, and each day secure passive motion. Make pronation and supination, flexion and extension, if only so much as you see me do; it will help to hold what ground we have gained.

Medical Societies.

NEW JERSEY STATE MEDICAL SOCIETY.

The one hundred and fifteenth annual meeting of the Medical Society of New Jersey was held at Long Branch, on May 24th and 25th, 1881.

The Society met in the parlor of the Ocean Hotel, on Tuesday, 24th, and was called to order at 8 o'clock P. M., by the President, Dr. A. N. Dougherty, of Newark. Vice Presidents Dr. L. W. Oakley, John W. Snowden, Stephen Wickes, and the other officers, were in their respective places. Rev. Mr. Young, of Long Branch, opened the meeting with prayer. The attendance of members of the Society was not as large as it has often been, although every district Society, with the exception of Salem and Sussex, was represented.

Dr. S. H. Hunt, of Etontown, President of the Monmouth County Society, extended a cordial welcome to the Society. He spoke of the Society of New Jersey as distinguished, not merely for its great age, but also for the many noble men who have been numbered among its members, who have left a record of grand triumphs in medicine, and whose memory is left to us fragrant with deeds of self-sacrifice and earnest life work.

In welcoming the Society to Long Branch he referred to the historic fame of Monmouth County, whose glory is to be perpetuated by a monument which will be an honor to the State, which shares in the fruit of her early sacrifices and patriotism. He referred also to the great advantages, both natural and artificial, which the county possesses. Its beautiful and far famed summer capital, with all its advantages of situation and climate, its health-giving atmosphere, and its unsurpassed beach, with a background of one of the richest and most productive agricultural districts to be found anywhere on God's earth, affording magnificent drives over excellent roads, skirted with pleasant villas and happy homes, to which the great cities on either side come, panting, from the summer heat. Dr. Hunt spoke most feelingly of the loss which the Society has sustained since its last meeting, in the death of Dr. Thomason, of Monmouth County, and while he mourned the loss of him and others like him, he rejoiced that the fruit of his active and honored life would live long after him.

The corresponding delegates were introduced to the Society by the Secretary, as follows:—

Dr. William Govern, from New York; Drs. W. H. Palmer and W. J. Burge, from Rhode Island; Dr. W. S. Babbit, from Massachusetts; Drs. G. Mott and C. K. Mills, from Pennsylvania; each of whom expressed feelings of cordial pleasure at being present. Drs. Wm. B. Atkinson and S. Cohen, of Philadelphia, being present, were invited to seats as corresponding members.

The President read the annual address, on the subject of

PLEURAL EFFUSION, WITH SPECIAL REFERENCE TO THAT OF PYOTHORAX.

His address began with a recital of fourteen cases of pleural effusion which he had treated or with which he had been conversant, and detailed all his personal knowledge of the subject, good and bad. His last case, one of pyothorax, was treated by the trocar and cannula, and by the drainage-tube introduced through the latter, the drainage-tube being lined for an inch and a half with a piece of silver catheter, for resting between the ribs, and a plate of silver with a tube and binding-screw, for the passage and securing of the drainage tube.

The history of the case, still in progress, went to show that this simple treatment was sufficient in at least some bad cases of empyema, and that it might be employed instead of the more dangerous methods in vogue, viz., per incision and injection.

The patient is getting well, wearing the tube without any inconvenience whatever, and never having had an injection used, or any antiseptic precaution taken. The President then went on to give the history of pleural effusions and their treatment, from the time of Hippocrates, down to and including the rib resection of Prof. Estlander. He introduced histories of cases furnished by Drs. Bleyle, Harvey, Corwin and Prof. Chew and others, and also tables of cases from the New York and Roosevelt Hospitals, concluding with a summarized recommendation of the best mode of treatment derived from his review.

On motion of Dr. Hunt, the following resolution was adopted:—

That during our present meeting the Standing Committee be directed to report upon the feasibility of lengthening the period of our annual meeting.

The various committees were then announced by the President.

Second Day.

The Society was called to order by the President at 9.30 o'clock.

On motion of Dr. E. M. Hunt, the following was adopted:—

Resolved, That a committee of five be formed, to be known as the Business Committee, who shall select subjects to be presented at each annual meeting, and the person and committee to present them, to whom shall be referred all voluntary communications offered, and said committee shall direct the hour and order of each paper and the discussion thereupon.

REPORT OF THE STANDING COMMITTEE.

Chairman, Jos. Parrish, M.D.

Two facts exist that render the study of the medical history of New Jersey for the past year of peculiar interest to the profession:—

First. The new law for regulating the practice of medicine and surgery, passed in the winter of 1880.

Second. The strong sentiment prevalent in favor of greater sanitary precautions in the prevention of disease, as instanced by the establishing of township health boards, and the increasing the powers of city boards of health.

A study of the various county reports reveals a greater prevalence of disease than during the preceding year. Throughout the State is noted an increase of malarial fevers, an increase which is apparent both in the number of cases seen, and in virulence of character. The tendency to remittent and continued forms and to typhoid complications is especially noted; also from many observers we have the record of increased medication necessary for combating these diseases. Quinine in large and repeated doses, the quantity in some cases being double the usual dose of the practice of fifteen years ago. In this connection may be mentioned that in various portions of the State have occurred numerous cases of puerperal fever, usually traced to malarial causes by the observer, often fatal, yet nowhere considered epidemic. Scarlet fever, diphtheria, whooping cough and measles seemed more prevalent than usual in most of the counties. During the latter part of the Winter and Spring there was an epidemic of rötheln, which seemed universally prevalent. It had few complications, and almost no mortality.

The epidemic of variola that has been present in New York and Philadelphia affected New Jersey but very slightly. Camden county reports 688 cases, of which 164 died. Essex reports a few cases, with 2 deaths. Hudson reports about 400 cases, with a mortality of 33 per cent. The proximity of these places to the cities mentioned accounts for the presence of the cases, but the number of them in Camden does not speak very well for the activity of the health authorities.

Numerous and varying were the answers to the question promulgated by the Committee as to the "cause of fevers." To formulate these answers is impossible, yet they furnish much subject for thought, and the Committee present the following conclusions as safe, if not decisive:—

The theory of marsh miasm, which includes the germ and spore theory, is not vindicated by the experience of residents in most of the seaboard counties of our State. No malarious diseases seem to be indigenous to the salt-meadows, cranberry-bogs, shore-springs and cedar-swamps which cover thousands of acres of New Jersey. Indeed, these regions are noted for their healthfulness. It is equally true that in elevated regions which are free from contaminated and obstructed water courses, where there is no marsh or accumulated organic matter undergoing decay, fevers of this type are common. Indeed, they occur at all seasons, and in almost every climate—on the open sea, in the sandy desert, and on the fruitless rock. If your students of etiology will study carefully the geography of malaria they will find this to be true, and with this discovery the natural suggestion may present itself to inquire into thermal and meteorological conditions for an explanation of at least some of the phenomena of malaria. Even quinine, the sovereign remedy, would be inefficient if we did not enjoin upon our patients the necessity of protecting the body against changes of temperature, and especially against the chili humidity of the night.

Observations regarding the use of the following new remedies were reported to the committee.

Dr. Fisler, of Gloucester, has used carbolic acid in the treatment of typhoid fever, with marked results. The Doctor uses three drops three times a day.

Dr. Victor Maolay, of Union, recommends the extract of quebracho, in five-grain doses, for asthmatic conditions.

Dr. Simpson, of Bergen, has employed the sulphide of calcium in a case of threatened suppuration in the neck, during the course of typhoid fever—with the result of reducing the swelling of the neck and the constitutional symptoms that accompanied it.

REMARKABLE CASES.

Dr. Thornton, of Burlington, reported a case of stenosis of the fauces following syphilitic ulceration; the obstruction was almost complete; an œsophagotomy was made, to relieve the condition, but the patient did not survive the operation. The Doctor also reported a case of cancer, with branny infiltration of the skin. Nearly the whole of the skin of the chest was involved.

Dr. Marcy, of Cape May county, communicated an interesting case of double uterus, with twin pregnancy. One child presented by the vertex, and was delivered naturally, the other, a vertex also, was delivered by podalic version.

Dr. Buckingham, of Gloucester, reported a case of a boy whose penis was attached to and embedded in the scrotum. He proposed to operate for the removal of the deformity.

Dr. Harold, of Essex, reported a case of double hare-lip, with protruding inter-maxillary bone and cleft palate. Photographs of the child before and after operation were also shown. The operation, by Dr. Pierson, consisted in paring the edges of the cleft lip, and pressing the inter-maxillary bone into the space between the superior maxilla, notching the vomer, to facilitate this movement. It was then secured in position by an interosseous suture, the soft parts were loosened at their attachments to the jaw, and were then brought together by pins and sutures; the result was a perfect lip, with a very good and continuous alveolar arch—the cleft palate was not operated on.

Dr. Burrage, of Essex, reported a case of acute pyæmia following labor, with recovery. During the progress of the case numerous abscesses appeared in the abdominal walls and the limbs, and the Doctor estimates that these abscesses discharged over four hundred ounces of pus, and the patient lost forty pounds of flesh. One feature of the disease was the absence of chills and profound sweats usually accompanying pyæmia.

Dr. Harvey, of Essex, reported a case of foreign body in the right bronchus, where immediate laryngotomy was made, without result. At the end of three weeks the foreign body, a nutshell, was discharged during a fit of coughing, together with an ounce of pus. A pneumonia followed the evacuation of the body, from which the patient completely recovered, with a sound lung.

In regard to the working of the new medical law, the Committee note that several of the district societies have appointed committees of registration, with a view of securing a complete record for their several counties, and publishing the same in the local papers. Warren county reports the law working favorably, and notes the disappearance of several irregulars.

In Patterson a test case was tried. The Registration Committee published a list of those who were practicing without diplomas. A person named Duclos was arrested and brought before the Recorder, on the charge of practicing without a diploma. Duclos was held, and the case sent to the Court of Sessions. Judge Woodruff there decided that he could not be held under the law, as Section 2 of the law distinctly states that the fine must be recovered in an action for debt, and that it was a civil and not a criminal charge.

The committee called the attention of the Profession of the State to the condition of the insane and of the insane asylums in the State. While these institutions are well conducted financially and beautiful architecturally, they are very meagerly supplied with apparatus for clinical and pathological research, consequently an immense amount of material that might be made extremely useful for the study of insanity and for the dissemination of knowledge of the subject among the faculty at large—for which there is certainly great need—has been allowed to lie in our great buildings, of little value to any one.

Both of the State asylums, through the instrumentality of the committee, have been supplied with such instruments of precision as will enable the staff of each asylum to supply, in future reports, valuable medical information on the specialty with which they have to do.

The committee recommend that each District Society appoint a Committee on Insanity, for the purpose of doing whatever may seem best, to relieve the people of New Jersey from the reproach that in most localities attaches to the County-house management of the pauper insane.

A valuable meteorological report was furnished, to condense which is impossible.

NECROLOGY OF THE YEAR.

Drs. T. J. Thomason, of Monmouth; C. R. Terhune, of Bergen; L. M. Crane, J. A. Cross and I. A. Nichols, of Essex; Louis Braun, of Union; J. F. Schenck, of Somerset; C. O. Gordon, of Ocean; J. W. McCullough, of Camden; Jos. Fithian, of Gloucester.

The following essays were read by title:—Menstrual Headache, Dr. H. A. Hopper. Carbolic Acid in Typhoid Fever, Dr. S. F. Fisher. Acute Peritonitis, Dr. J. C. Johnson. Two Cases of Perityphlitis, Dr. Stephen Pierson. Etiology, Symptomatology and Preventive Treatment of Pulmonary Phthisis, Dr. P. C. Barker. Camden Sewers, Dr. J. H. Wroth. History, Origin, etc., of the Epidemic of Typhus Fever in the Camden Almshouse, by the Staff. Acute Pyæmia following Labor, Dr. R. L. Burrage.

The Corresponding Secretary made a formal report.

Delegates to Corresponding Societies read their reports, which were received and referred to the Committee on Publication. Dr. L. W. Oakley and Dr. Jas. S. Green, to American Medical Association. Dr. E. P. Townsend, to Pennsylva-

nia Medical Society. Dr. D. E. English, to West Jersey Medical Society.

The following persons were appointed by the President, on the Business Committee: H. R. Baldwin, E. J. Marsh, S. T. Thornton, E. M. Hunt, and J. L. Bodine.

The degree of Doctor of Medicine was conferred upon Dr. Charles Vogler, of Newark, he having complied with the requirements of by-laws.

Dr. S. Wickes, of Orange, read a paper, his subject being "A Twenty-five Years' Review."

LACERATION OF THE CERVIX UTERI.

Dr. G. H. Bulloray, of Paterson, read an essay on "Laceration of the Cervix Uteri." He referred to the frequency of the lesion, and its importance as a cause of uterine disease in those who have borne children. He also referred to the frequency with which the lesion is misappreciated by general practitioners in this country, and also by specialists in Great Britain, Ireland and France. In proof of the correctness of the latter statement he said he had seen, in one day, in the out-patient department of a large special hospital for women, in London, thirteen cases of laceration of the cervix, not one of which was diagnosed as such. In reference to the cause of uterine cervical laceration, Dr. Bulloray says that, in a large proportion of the cases he has met with, the labor in which the laceration occurred was very rapid, in many, delivery being accomplished before the arrival of the accoucheur. Dr. Bulloray does not agree with Dr. Goodell, of Philadelphia, who thinks that meddlesome midwifery plays an important part in the production of this accident. He thinks that the cervix, like the perineum, will sometimes rupture in spite of all preventive measures. He does not think that the forceps, when properly applied in appropriate cases, materially increases the risk of the occurrence of laceration of the cervix. The chief point of interest in the essay is in reference to the relation existing between laceration of the cervix and cancer of that portion of the uterus. Out of thirty-seven cases of cancer of the uterus examined by the author, with special reference to this point, twenty-one were found to have previously suffered from laceration of the cervix. In many of the remaining cases the disease was so far advanced that it was impossible to ascertain whether or not any laceration existed. In the operation of hysterotomia, Dr. Bulloray recommends the use of silver wire or silk woven gut sutures; he is opposed to the use of silk because it has proved unsatisfactory in his hands. He does not endorse the recommendation of those who advocate sewing up a woman's cervix uteri in the physician's office or at the dispensary, and then sending her home to take care of herself until she returns to have the stitches taken out.

A NEW DISTRICT SOCIETY CREATED.

An application, in due form, being presented by the physicians in Atlantic county, for the establishment of a District Society in that county, it was voted that a commission be issued.

Dr. C. J. Kipp read a very interesting and instructive paper on Eye Affections from Malarial Poisoning.

Intermission for lunch at one o'clock, P.M. At 2 o'clock the Society re assembled.

ELECTION OF OFFICERS.

The committee on nomination reported as follows:—

For President, L. W. Oakley. *First Vice President*, J. W. Snowden. *2d Vice President*, S. Wickes. *3d Vice President*, P. C. Barker. *Corresponding Secretary*, Wm. Elmer, Jr. *Recording Secretary*, Wm. Pierson, Jr. *Treasurer*, W. W. L. Phillips. *Standing Committee*, Jos. Parrish, C. J. Kipp, S. C. Clark. (Dr. Parrish afterwards declined, and Dr. E. J. Marsh was added to the committee.)

Delegates to American Medical Association—Drs. Hopper, Parrish, Ridge, Elmer, A. Coles, Halsey, Gordon, Ward, D. C. English, R. R. Conover, E. P. Cooper, D. L. Disbrow, Marsh, Field, A. J. Coles.

Delegates to International Congress—Drs. A. W. Rogers, E. M. Hunt, H. W. Hopper, John Wolverton, E. Holden.

Delegates to Medical Society of Massachusetts—Drs. G. H. Bulloray, J. L. Bodine, C. J. Kipp.

Delegate to Medical Society of Rhode Island—Dr. S. Disbrow.

Delegates to Pennsylvania Medical Society—Drs. R. H. Page, J. D. Heritage, J. W. Snowden.

Delegates to Medical Society of New York—Drs. T. R. Varick, D. St. John.

Delegates to Connecticut Medical Society—Drs. J. C. Herrick, J. B. Wainwright.

The report was adopted and the ticket recommended was duly elected.

It was decided that the next annual meeting of this Society should be at Asbury Park.

It was voted that the assessment for the next year should be two dollars per capita.

Dr. W. J. Chandler, of South Orange, was appointed essayist for the next meeting.

It was voted that the hour for meeting shall be four o'clock in the afternoon, and that the Secretary be instructed to prepare the programme in accordance with the plan proposed by the Business Committee.

On motion of Dr. H. R. Baldwin, it was voted:

Whereas, The position of honorary membership to the New Jersey State Medical Society has, for the past century, been granted with extreme caution, and,

Whereas, Of late years, a reprehensible laxity has grown up in the proposal of names (though highly honorable in themselves) scarcely up to the required standard; therefore, be it

Resolved, That a standing committee of three Fellows be appointed, to which all nominations for honorable membership shall be referred, and who shall report at the next annual meeting; that the committee be appointed by the President, and that it shall continue in office for three years.

Drs. H. R. Baldwin, S. H. Pennington, E. M. Hunt were appointed on the committee.

The reports from the Committee on Honorable Membership received at this meeting were referred to the Committee.

It was voted that a committee be appointed to report upon the comparative values of human-

ized virus and bovine virus, and the best security of their purity, and that the reporters of each district medical society shall transmit to the chairman of the committee the facts and opinions of the district society.

Dr. S. Wickes was appointed a committee to report upon the condition of the hospitals, infirmaries, dispensaries, and insane institutions in this State.

Dr. Newton, of Paterson, read a short paper on the adulteration of milk.

The Society then adjourned.

Editorial Department.

Periscope.

The Treatment of the Diarrhœa of Phthisis.

At a recent meeting of the Medical Society of London, Dr. C. Theodore spoke on this subject. He enumerated three different varieties met with in that disease, 1st. Disease from the primæ viæ. 2d. Diarrhœa from ulceration of the intestines. 3d. Diarrhœa from lardaceous disease of the intestines. The first was due to over-feeding, an error often committed in the treatment of phthisis, but easily remedied. The second was the most serious form, often proving fatal. Intestinal ulceration was detected after death in five-sixths of Louis' cases, in sixty-seven per cent. of Lebert's, and eighty-one per cent. of the Brompton Hospital cases, the amount of mucous membrane involved varying in different cases. The small intestine appeared to be the first attacked, and especially the neighborhood of the ilio cæcal valve. The stages of the disease consisted of, (1) Inflammatory hyperplasia of the solitary and agminate glands; (2) their conversion into small abscesses, or their caseation; (3) the discharge of their contents, leaving behind ulcers with smooth floors and sharp edges; (4) formation of gray tubercle in floor of ulcer, and its subsequent caseation, leading to extension of the ulcer, and its junction with neighboring ulcers, until the whole intestine becomes a mass of ulceration. Thickening of the peritoneal coat generally takes place in the vicinity of the ulcer, and thus perforation was not common. Sometimes, however, it takes place and sets up local or general peritonitis, ending in death. Occasionally, ulceration into a small vessel causes alarming hemorrhage, and is known to heal, leaving a thickened scar, which causes a constriction of the intestine. The clinical symptoms of ulceration were persistent diarrhœa, tongue characteristic of great irritation, pain in the abdomen, tenderness over the ulcerative process, and rapid wasting. Tenderness was, in the author's experience, more common in the left iliac region than in the right. The disease appeared in the small intestine, but created greater ravages in the large one, and advanced rapidly, and this was to be accounted for by the traction on the ulcers from the changes in the size of the colon during digestion, by the slow progress of the fæces and the disengagement of foul gases in this region, giving rise to conditions unfavorable to the healing of ulcers. Pyrexia depended upon the amount of ulceration. If only a limited surface was attacked it was absent, but if large tracts were involved the chart showed great extremes and marked fitfulness. Ulceration might exist without causing diarrhœa, but such cases were rare. The forms of diarrhœa in phthisis arising from lardaceous disease corresponded with colliquative diarrhœa. It prevailed in the latter stages of the disease, and often alternated with the profuse night sweats. It differed clinically from the ulceration in the state of the tongue and nature of the stools, and was not necessarily attended with pain. The chief feature was the infiltration of the tissues, and especially of the villi and their vessels, with lardaceous material. The treatment of the first form was by alterative and antacid medicines and careful regulation of diet; treatment of the second form must be directed toward treating the ulcers, and consisted of rest in bed; the use of bland non-irritating food, counter-irritation to abdomen by poultice or blister; opium and sulphate of copper by mouth, or, if large intestine be involved, by opiate enemata combined with astringents and sometimes antiseptics. Morphia suppositories or injections containing opium were useful. Treatment of third form chiefly by astringents.

On the Treatment of Eczema.

The *Concours Médicale* publishes an article on the above subject, from which we make the following extract:—

The great *desideratum* in the therapeutics of eczema would be to have some specific remedy that would reach the very cause of the disease. The discovery of this specific has often been announced, but the hopes of both physicians and patients have always been deceived, and to this day nothing of the kind is known.

Among the many remedies which have been suggested, we shall indicate a few of those that have remained in some degree of favor.

1st. In the first rank we find the vegetable depuratives—bitters. In that long list of drugs there were two held in great esteem, but deservedly forgotten now: elm bark and Asiatic penny-wort.

2d. The second place is occupied by purgative medication. It is one of the oldest forms of treatment in use, and still has a few partisans. Let us note this difference: in purging their patients, old time doctors intended expelling the *peccant humor;* now, a purgative is only considered as a revulsive agent. A purgative is given once a week, or a laxative is taken every other day, but unless called for by special indications, this method should not be resorted to,

as it has no effects, either on the manifestations or the duration of the disease.

3d. The diuretic method is open to the same, and even more severe criticism.

4th. Sulphur deserves special mention, because great allowances are to be made in taking the opinion expressed by Alibert, that "sulphur is the mercury of herpes." Sulphur is only useful in two cases; when eczematous patients have bronchial catarrh, or when they are of a lymphatic temperament.

5th. All cutaneous derivatives, in the form of blisters, setons, etc., do not answer the intended purpose, and are besides dangerous, because they may give rise to new eczematous developments.

6th. In fact, among the many therapeutic agents directed against eczema, but one really deserves attention; this is arsenic. It has been praised by some, and condemned by others; its effects are certainly not very marked, and it is not a specific, yet it renders valuable service.

To obtain the best results from this remedy, we must know how to use it, and to that end, we must observe the three following indications:

1st. Arsenic should be given at the proper time.

2d. It must be given in really active doses.

3d. It must be given for a long time, and continued far beyond the period of cure.

The proper time for its exhibition is during the period of dryness, in the non-inflammatory stage, for it has no effect on eczema when either acute or oozing. It is inert unless given in really active doses, hence the remedy is so often without effect, because both patients and doctors are afraid of arsenic. An active dose of Fowler's solution is twelve drops as a minimum, rapidly increasing to fifteen, twenty and twenty-five drops; while for arseniate of soda the daily and progressive dose is one, two, three and four centigrams (gr. 0.15, 0.30, 0.45 and 0.60). Finally, its use must be continued for months, care being taken to interrupt it, for example, every three weeks, during which time a purgative may be given, if judged necessary. After eczema has passed, arsenic should still be occasionally taken, say two or three times a year, and this continued for years.

This treatment of eczema by arsenic reminds us of syphilis treated by mercury. In both those ailments it is well to remember the adage: chronic disease must be met by chronic medication.

The general treatment of eczema is not limited to this remedy alone. Other methods are to be employed, according to the several indications presented by the disease. Chief among these is the patient's temperament. The lymphatic and arthritic types are those which most favor eczema. The first is to be corrected by the use of iodide of iron (three to six spoonfuls of the syrup daily), cod-liver oil and bitters; against the last we should prescribe arsenic, bicarbonate of soda, and alkaline mineral waters. The physician must endeavor to ascertain the causes which may have developed the disease, so as to suppress them. This will require minute enquiry into the patient's private life. He must also prescribe a regimen or hygiene, which may vary according to cases and subjects, but which should include the following points, neglect of which will always be dangerous: a quiet, regular and abstemious life; all excitants must be avoided; salt water fish, shell fish, and pork meat discarded. Alcoholics of all kinds must be shunned, as also excesses (of work, late hours, or pleasures). All causes of stimulation for the skin, such as frequent and protracted baths, extremes of temperature, sea air, etc., must be avoided. And these observances must be continued during the balance of the patient's life.

We have made no allusion to mineral waters in the treatment of eczema; we reserve this question for a review of the general treatment of herpes.

Hard Chancre of Lip.

The following singular cases are reported in the Glasgow *Medical Journal*. They illustrate how innocent persons may become syphilitic:—

M. M., æt. 22, saleswoman, was admitted 29th October, 1880. She is a strong, healthy girl, and seems to have been unusually exempt from illness throughout life. About six weeks previous to admission into hospital, a small hack appeared in the middle of the upper red lip; this became painful and inflamed, and ultimately an open ulcer formed, and gradually spread over the lip, defying all treatment.

Condition on Admission.—Occupying the middle of the upper lip was a raised ulcer, circular, and about the size of a shilling; its base was hard and cartilaginous, and the forepart was covered with a scab. Free movement of the lip caused pain and bleeding. The entire lip was thickened and everted, and the glands behind both angles of the jaw and under the chin were enlarged. There was a distinct measly rash over the lower part of the chest and abdomen.

The patient was quite ignorant of the real nature of the sore, but its appearance was perfectly characteristic, and if any doubt had existed it would at once have been removed by the presence of the secondary eruption, about which, too, the patient was quite ignorant.

Treatment.—The ulcer was merely protected, and bichloride of mercury and chlorate of potash administered internally. On 15th of November it was noted that the base of the ulcer was less firm and cartilaginous, and the measly rash was fading. By the 17th the ulcer began to diminish in size, and a healing line could be seen. On the 18th it was dressed with a solution of potassio-tartrate of iron. When patient left, on the 21st, the ulcer was perfectly healthy, was much smaller, and the effusion into the surrounding tissues rapidly subsiding. On the 29th, having continued the medicine meanwhile, she returned to report progress; the ulcer was completely healed, but the thickening had not entirely dispersed, and the gland still remained enlarged. All eruption had gone.

Dr. Macleod had a second case in the hospital some time ago, with an almost identical history. The patient was a healthy young servant. The nature of the sore was recognized on admission, but only local treatment was employed till the secondary syphilitic eruption appeared. The roseola was very plentiful and characteristic, and it and the sore (for which, before admission, many useless local applications had been tried), both disappeared quickly under the use of the bichloride of mercury.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The claims of Ventnor, Isle of Wight, as a health resort, are set forth by Dr. W. T. Parker, in a reprint from the New York *Medical Journal*. He thinks it deserves special attention from Americans, as there they escape the social boredoms so frequent in most of the resorts nearer home.

——A timely and judicious paper has been published by Dr. Clifton E. Wing, of Boston, with the title "On Unnecessary Surgical Operations in the Treatment of Diseases of Women." He begins by intimating that a good many of these operations are performed when not at all, or at least not strictly necessary, because the fees are greater for "a surgical operation" than for the treatment of cases by more simple means. He maintains, and we think with entire justice, that many of the gynæcological operations now in vogue can often be avoided with advantage to the patient.

——Our space permits us only to name the following reprints, etc:—

A case of Primary Tuberculosis of the Larynx, by Dr. J. Solis Cohen, of Philadelphia.

Constitutional Syphilis, by Dr. G. M. B. Maughs, of St. Louis.

Address at the Opening of Pardee Hall, by Dr. Francis A. March, of Easton.

Prospectus of the American Hospital for Skin Diseases, Philadelphia.

Annual Report of St. Joseph's Hospital, Philadelphia.

Statistical Report of 252 cases of Inebriety, by Dr. L. D. Mason, of Fort Hamilton, Long Island.

Report of the Asylum for Persons Deprived of their Reason, Frankford.

Report of the State Lunatic Asylum, Utica, New York (from Dr. John O. Gray).

——Dr. J. Adams Allen's Commencement address at the Rush Medical College, Chicago, is written with the customary vigor of that veteran practitioner, orator and journalist. Pity that it has so many typographical errors. The Secretary's Report contains some interesting statistics of the College. It appears that during last winter's session there were in attendance at the College, 170 gentlemen in the graduating class, 319 under graduates, and 16 students pursuing special studies, making a total of 505 matriculates. The number of students attending lectures during the past five years has been:—In 1876-7, 306; in 1877-8, 382; in 1878-9, 364; in 1879-80, 471; in 1880-1, 505. When, to the number of students, is added the number of matriculates present in the Practitioners' Session, to be held in April, it is stated that by far the largest number of matriculates ever recorded in any one fiscal year, in a medical college in the West, will be contained in the Rush's commencement for 1881-2.

——Some months ago (Reporter vol. xliv, p. 298) we described a "nine-cent dinner," in that incomplete language and indefinite manner which was as much as could be expected of a masculine quite uninitiated in the mysteries of the kitchen. Needless to say, our description was generally received as a well-meant effort of the imagination; or as a display of ignorance of economics, to be pitied rather than blamed. We are glad to announce, therefore, that the amphitryons of the occasion, the accomplished ladies who preside over the New Century Cooking School, 1112 Girard Street, Philadelphia, have come to the rescue of their guests, and describe, in a neat pamphlet of 31 pages, "How We Made a Nine-cent Dinner," and have added to that pamphlet the explanation of "some other economies," and, in fact, a lot of other matters full of interest to the sagacious housekeeper. We heartily recommend every reader to get this little publication for his own family and his friends, which can be done by enclosing ten cents to the address given.

——In a reprint on the preventable causes of insanity, Dr. H. Wardner, of the Illinois Southern Hospital for the Insane, divides the immediate mental causes into three groups:—1, shock; 2, prolonged strain; 3, bad mental habits (as violent temper, etc). The great preservative he recommends is "constant, sufficient, but not excessive occupation." He adds a valuable warning on this subject:—

> In illustration of the ill effects of the lack of this, I need only refer to that tendency which is more common among women than among men, to depression of spirits.
>
> This dire affliction, for no physical pain is more to be dreaded, is frequently attributable to, and is always aggravated by a lack of healthy mental occupation. It is because men have more constant occupation than women, that they are free from this fruitful source of mental alienation.
>
> The remedy lies greatly in the larger intellectual cultivation of your daughters; the substitution, perhaps, of lessons designed to awaken in them a love for literature as an unfailing source of healthful mental occupation, in place of the drill that is now so much given them in technical school-book study.

——Of the numerous short monographs and

reprints lately received several bear on the matter of specialties in medicine. Prof. Bartholow, of the Jefferson Medical College, has chosen to refer to the cultivation of such special branches, in words far from those of approval; in fact, quotes in relation to them some very abusive terms from the Roman medical writers, the application of which to modern specialism is utterly out of place. Certainly he must have known that there is no similarity whatever between the quacks of Ancient Rome and the learned specialists of to-day; and knowing it, the inference he left his hearers and readers to draw was a very unjust one.

On the same subject we have an address by Dr. E. C. Seguin, of the College of Physicians and Surgeons, New York. This is in much better tone, as the following extract toward the close will show:—

In this address I have endeavored to show that the growth of specialties has been normal, and in accord with the general scientific movement of the age; that specialties are useful to the public and to medical science; and that the practice of a specialty is not unattended by intellectual dangers.

BOOK NOTICES.

A System of Oral Surgery; Being a Treatise on the Diseases and Surgery of the Mouth, Jaws, and Associate Parts. By James E. Garretson, M.D., D.D.S., Dean of the Philadelphia Dental College, etc. Illustrated with numerous steel plates and wood-cuts. Third Edition, thoroughly revised, with additions. Philadelphia: J. B. Lippincott & Co., 1881. Cloth, 8vo, pp. 916.

The fact that a third edition of this exhaustive treatise on oral surgery has been called for, is the best indication of the favorable reception of former editions, and shows how fully the labors of its author have been appreciated by the profession on both sides of the Atlantic. In the present edition the text has been almost entirely rewritten, and much new matter, including some two hundred additional cuts, has been added. The work throughout is characterized by a thoroughly systematic arrangement, the subject being divided into two parts, treating respectively of *dental art* and of *special surgery*, thus advancing progressively from the purely mechanical to the scientific, from the simple to the complicated. It would be impossible for us, in the limited space allotted to book reviews, to do full justice to a work of such magnitude, and treating of so comprehensive a subject; but we wish especially to draw the attention of surgeons and dentists to the importance which the author attaches to the early recognition and correct diagnosis of malignant tumors situated about the mouth or adjacent regions. The author says that every foreign growth or ulcer which cannot be otherwise accounted for should be regarded as malignant, and that the patient's only chance of recovery lies in its early removal. He holds that cancer begins as a local disease, and afterwards becomes constitutional; hence, the importance of early diagnosis. In epithelioma of the face he advocates the thorough removal with the knife of the diseased tissue, the seat of the ablated part to be occupied by structure brought from neighboring or distant parts. A large number of cases are recorded, giving to the theories advanced the weight of clinical experience. In the final chapter the subject of anæsthesia receives full consideration. The illustrations, numbering five hundred and forty-one wood-cuts and nine steel plates, are well executed. The book unquestionably deserves a place in the library of every English speaking dentist or surgeon.

A Treatise on the Continued Fevers. By James C. Wilson, M.D., Physician to the Philadelphia Hospital and to the Hospital of the Jefferson Medical College, and Lecturer on Physical Diagnosis at the Jefferson Medical College, etc., etc. With an introduction by J. M. Da Costa, M.D., Professor of the Practice of Medicine and Clinical Medicine at the Jefferson Medical College; Physician to the Pennsylvania Hospital, etc. etc. New York: Wm. Wood & Co., 27 Great Jones street, 1881. Cloth. 8vo. pp. 365.

The volume before us constitutes the April number of Wood's Library of Standard Medical Authors. The introduction, by Prof. Da Costa, on *The Management of Fever*, is characterized by the usual clearness of expression and profound philosophical thoroughness of that distinguished physician and teacher. The lesson he here teaches is well worthy of the careful study of every physician and student. The author treats of the various forms of disease known as continued fevers, in a more elaborate manner than is usually found in text-books on practice, and the work must be regarded as a valuable addition to medical literature. It is especially, we should say, designed for the use of practitioners who have already had considerable experience, being rather too comprehensive for students. The purely mechanical execution of these volumes shows an improvement on last year.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE. — COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS. — MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS. — SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

RECENT MEDICAL LEGISLATION.

Slowly, but, on the whole, as rapidly as could be expected, when we reflect what kind of material most State Legislatures are made of, the attention of our law-making bodies is turning to providing health boards, protecting the people against unscrupulous quacks, and prohibiting the adulteration of articles of food and medicine, and the sale of diseased and dangerous flesh and grains.

In Indiana a bill has been passed establishing a State Board of Health, defining its purposes, powers, and duties, providing a system for the registration and report of vital and sanitary statistics, and prescribing the duties of various civil officers in relation thereto. Five thousand dollars a year is the appropriation—a very insufficient sum, but enough to begin on. We quote a few sections to show the scope and purpose of the Board:—

SEC. 2. The State Board of Health shall have the general supervision of the interests of the health and life of the citizens of this State. They shall especially study the vital statistics of this State, and endeavor to make intelligent and profitable use of the collected records of deaths and of sickness among the people. They shall make sanitary investigations and inquiries respecting the causes of disease, and especially of epidemics, the causes of mortality, and the effects of localities, employments, conditions, ingesta, habits and circumstances on the health of the people. They shall, when required, or when they deem it best, advise officers of the government, or other State boards, in regard to the location, drainage, water supply, disposal of excreta, heating and ventilation of any public institution or building. They shall, from time to time, recommend standard works on the subject of hygiene, for the use of schools of the State; and it shall be the duty of the board to examine into the purity and chemical qualities of the intoxicating liquors used as a beverage in this State, and report what, in their best judgment, is the effect of the use of such intoxicating liquors as a beverage upon the industry, prosperity, happiness, health and lives of the citizens of the State. They shall, prior to the 15th day of November of each year, make a report to the Governor of their doings, investigations, and discoveries during the year ending on the 31st day of October next preceding, with such suggestions in regard to legislative action as they may deem important.

SEC. 11. The clerk of the Circuit Court of each county in this State shall be required to keep a book especially prepared and set apart for the registration of name and post office address of physicians and accoucheurs of their county. And it shall be the duty of such clerk to report

to the health officer of the county, on or before the fifth day of each month, the number of certificates of marriages that have been recorded during the preceding month, together with the names of parties contracting such marriage and the date when such marriage was solemnized: *Provided*, That the clerk shall be entitled to charge each physician and accoucheur so registered a fee of ten cents and no more, and the County Commissioners shall allow such clerk fifty cents, and no more, for each monthly return made to the health officer of said county.

Sec. 12. It shall be the duty of the board of health of each county to keep a complete record, according to the form prescribed by the State board, of all marriages, births and deaths reported to them under the provisions of this act, and such record shall be open to the inspection of any citizen, without fee.

The fine for a physician refusing to register is not more than ten nor less than five dollars.

Tennessee has passed a registration law providing for the registration of all births, marriages and deaths. They are to be made up by the clerk of the county court and transmitted annually to the Secretary of State. In cases of death, the date, sex, color, age, place and disease are to be stated.

Arkansas has appropriated four thousand dollars to pay the Secretary of the Board of Health and the expenses of the Board. Its duties are defined, similarly to those of Indiana. But a registration of physicians is not contemplated; and it appears to be placed more directly under the control of the executive to act as a body for investigating special causes of disease, and such sanitary questions as may at any time arise, and be of general importance to the commonwealth. Thus two of the sections read:—

Sec. 8. At any time, the Governor of the State may require the State Board of Health to examine into nuisances or questions affecting the security of life and health in any locality, and in such case the said Board shall have all necessary powers to make such examinations, and it shall report the results thereof to the Governor, within the limits of the time which he shall prescribe for such examination

Sec. 10. Said Board may, from time to time, engage suitable persons to render sanitary service, and to make or supervise practical and scientific investigations and examinations requiring expert skill, and to prepare plans, and report relative thereto. And it is hereby made the duty of all officers and agents having the control, charge, or custody of any public structure, work, ground, or erection, or of any plan, description, outlines, drawings, or charts thereof, or relating thereto, made, kept, or controlled under any public authority, to permit and facilitate the examination and inspection, and the making of copies of the same by any officer, or person by said Board authorized, and the members of said Board, and such other officers or persons as may at any time be by said Board authorized, may, without fee or hindrance, enter, examine, and survey all grounds, erections, vehicles, structures, apartments, buildings and plans whereby the public health may be promoted, or in any wise preserved.

In New Jersey an act has been passed (approved March 25), placing in the hands of the State Board of Health authority to take cognizance of the interests of the public health as it relates to the sale of food and drugs, and the adulteration of the same, and make all necessary investigations and inquiries in relation thereto.

The act reads:

1. *Be it enacted by the Senate and General Assembly of the State of New Jersey*, That no person shall, within the State of New Jersey, manufacture, have, offer for sale, or sell, any article of food or drugs which is adulterated, within the meaning of this act, and any person violating this provision shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding $50 for a first offence, and $100 for a second and subsequent offences.

2. *And be it enacted*, That the term "food," as used in this act, shall include every article used for food or drink by man, and that the term "drug," as used in this act, shall include all medicines for internal or external use.

Drugs are defined to be considered adulterated under the following conditions: —

First. If when sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality or purity laid down therein.

Second. If when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia, or other standard work on materia medica, it differs materially from the standard of strength, quality or purity laid down in such work.

Third. If its strength or purity fall below the professed standard under which it is sold.

It will be noted that these are rather stringent conditions, and if fully enforced would materially limit the sales of some of the wholesale drug houses, or else alter their modes of conducting business.

Ohio, this winter, added some sections to her revised statutes which will make it troublesome

for the projectors of bogus colleges to run their institutions inside of her borders. We quote them from our contemporary, the *Lancet and Clinic*:—

Section 4403*a*. Whoever shall make, issue or publish, for purpose of sale, barter or gift, any certificate, diploma, or other writing or document, falsely representing the holder or receiver thereof to be a graduate of any medical school or college, or of any educational institution of medicine whatsoever, and entitled to the powers, privileges, or degrees thereby pretended to be conferred; or whoever shall sell, or otherwise dispose of, or offer to do so, any such diploma, certificate, writing or document, containing the false representation aforesaid; or whoever shall use his name, or permit the same to be used, as a subscriber, for any purpose or in any capacity, to such false and fictitious diploma, certificate, writing or document aforesaid; or whoever shall engage in the practice of medicine and surgery under and by virtue of such fraudulent diploma, certificate, writing or document aforesaid, shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be subject to the penalty prescribed in Section 4403*b*.

Section 4403*b*. Whoever shall make, issue, or publish, or cause to be made, issued, or published, for the purpose of sale, barter or gift, any diploma, certificate or writing, representing the holder thereof to be a graduate of any medical school or college, or of any educational institution of medicine whatsoever, unless such holder shall have, in fact, attended a complete course of instruction in such school, college or institution for medical teaching, equal to the average course of instruction in other schools, colleges or institutions where the various branches of medicine are taught as a science, in good standing in the state of Ohio, shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be fined in any sum not exceeding one thousand dollars, nor less than one hundred dollars, or imprisoned in the penitentiary not more than three years, nor less than one year, or both, at the discretion of the court.

Ohio has not yet a board of health, nor a registry system, but certainly she will not long remain without these important proofs of civilization.

This by no means exhausts the list of medical laws which have been enacted this past winter; but references to the others we shall have to reserve for a future occasion.

There is no real difficulty in obtaining proper medical legislation in any State, provided that the majority of physicians are earnestly interested in having it. As a class, they can bring effective influence to bear on the members of Assembly; but it is only too obvious that there prevails a regretable lethargy among them which prevents the active legislation so much to be desired.

Notes and Comments.

Tinctura Magnoliæ Acuminatæ in the Treatment of Gastric Intermittent Fever.

In an article on the above disease, published in the *Southern Practitioner*, for May, Dr. A. E. Beresford, of East Springfield, Ohio, recommends in high terms the tincture of the Magnolia Acuminata (cucumber tree).

The preparation he prefers is a tincture of the fresh bark of the root; although he has used a tincture of the ripe fruit considerably. He does not pretend to say that it will cure all cases of intermittent fever, as the different forms of intermittent fever require different treatment; but in this particular form of the disease, he asserts that it is followed by better results than any of the *Salts of Cinchona*.

He usually commences the treatment with a preparative dose of podophyllin and leptandrin, or the following powder, viz:—

℞.	Podophyllin,	gr. ss	
	Leptandrin,	gr. j	
	Bitartrate of potassa,	gr. iv.	M.

Divide into four powders.

Sig.—One every three hours until the bowels are moved.

He then gives the tincture of magnolia acuminata, in tablespoonful doses every three or four hours, until the fever is arrested; and then in wineglassful doses every morning before breakfast, for some time after, to prevent a recurrence of the disease.

His opinion is, that the magnolia acts: first, as a sedative, by allaying the irritation of the gastro-intestinal mucous membrane. Second, as an antiperiodic, in breaking up the periodical tendency of the disease, which it has never failed to do in his hands—if given in sufficiently large doses—in two or three days' time.

Third, as a tonic, in strengthening the digestive and assimilative powers, and giving general tone to the system.

The Value of Local Treatment in Syphilitic Ulceration of the Larynx and Pharynx.

Dr. J. D. Arnold, of Baltimore, writes from Vienna, to the *Maryland Medical Journal*, May 15th, giving the history of several cases treated at the Vienna Clinic, in illustration of the above. The treatment from which he has seen most satisfactory results consists in penciling the face of ulceration with the following solution:—

℞.	Iodidi potassii,	0.5	
	Iodinii puri,	0.3	
	Glycerini,	40.00	M.

The diseased surface having been thoroughly cleansed of all secretion by careful washing with a weak solution of copper sulphate, the iodglycerine is applied with the brush, *two* or *three* times *daily*, while the infiltrated edge of the ulcer is occasionally touched with silver nitrate fused upon a metal sound.

The Rhus Aromatica (Fragrant Sumach).

In the May number of the *American Journal of Pharmacy*, Mr. H. W. Harper has a well written paper on this indigenous plant. He states it is recommended especially for enuresis and hemorrhage, and adds:—"Since its introduction many physicians have tested its virtues, and their statements corroborate those of the discoverers. That it is an efficacious remedy in the treatment of *enuresis* there can be no doubt, for the author of this essay has seen it tried with success in several cases. A tincture containing the oleoresin, acid resin, gallo-tannin and extractives of the crude drug, and representing four troy ounces to a pint of stronger alcohol, may be made by macerating the ground drug in the menstruum for seven days, with frequent agitation, and then percolating until one pint of tincture is obtained. It is obvious that preparations of Rhus aromatica should not be mixed with solutions containing salts of iron."

The dose of the powdered drug is from 20 to 60 grains (gm. 1.3 to 4.0); the fluid extract 5 to 40 drops (gm. .3 to 2.5); the tincture 20 drops to a teaspoonful (gm. 1.0 to 4.0) given in water and repeated as often as necessary. As a topical remedy to control hemorrhage a decoction of the bark will be found efficacious.

Curious Facts in Physiological Magnetism.

The French Association for the Advancement of Science met last month. Among other interesting papers presented was one by M. Ziegler of Geneva. This observer believes that he has discovered that two magnetized bars of metal, joined together in a certain manner, produce certain definite effects upon animals submitted to experimentation, which differ according to the angle of intersection. One of these bars can be replaced by terrestrial magnetism. It is concluded that terrestrial magnetism radiates in the same way as light or heat, and that its rays are refracted in passing through certain bodies, such as crystals and iron. The physiological effect of magnetism can be shown by concentrating its rays through a lens of soft iron on the heart of a rabbit, when circulatory disturbances will occur. Violent peristaltic movements are provoked by focusing in the same way the magnetic rays on the intestines. M. Carl Vogt, who read the paper, states that he has himself observed the effects produced on the bowel, and, without giving any theoretical explanation of their mechanism, he believes that the discovery will lead to important results in physics, physiology, and medicine.

Diagnosis of Coxalgia.

The Paris correspondent of an English contemporary states that—

M. Cazin, of the Marine Hospital of Berck-sur-Mer, has published his researches on the Exploration of the Hip-joint per Rectum. He states that, in young subjects, the finger can always recognize a quadrilateral space corresponding to the cotyloid cavity, and which it is proposed to call the "post-cotyloid surface." This mode of examination, hitherto reserved for special cases, should in future form part of the investigation in every case of coxalgia. In ninety-six cases of hip-joint disease observed by M. Cazin, rectal exploration has furnished information in forty-seven instances. The signs which can thus be noted are: pain on pressure of the post-cotyloid surface, hypertrophy of the intra-pelvic ganglia, general increase in size of the osseous surface, depression, erosion, flexibility, mobility, destruction and perforation of the post-cotyloid surface; doughiness of the soft parts, abscesses of different kinds, etc. M. Cazin believes that this method of examination will render the diagnosis of coxalgia in early cases a matter of much greater certainty.

Contagion from Milk.

As the results of a recent careful study of this subject, Mr. A. H. Smee, of London, says that the food of milch cows affects the quality of the milk; that milk can be a vehicle of contagion in three ways—by direct communication through the water used for adulteration, or for cleansing; by absorption through the exposure of the milk to deleterious gases; and in extreme cases by alterations in the milk itself from altered secretion in diseased animals. The methods which are now employed are not sufficiently delicate to detect the minute changes which take place in milk.

—"I half agree with you," said old Piper Heidsick to the homœopathic doctor. "It is just as you said just now, '*similia similibus* decanter;' but I prefer larger doses than you give in your school."

Special Reports.

NO. XI.—INSANITY.

(*Concluded from page* 642.)

The Genesis of Hallucinations.

We note, from the London *Medical Record*, that in The *Rivista Sperimentale di Freniatria e di Medicina Legale*, Anno vi, Fasc. 1 and 2, Professor Tamburini discusses the genetic source of hallucinations at some length, and concludes as follows:—

1. Hallucinations necessarily have their seat in the sensory cortical centres, where the impressions received from the organs of the senses are perceived.

2. Hallucinations consist of a morbid excitement of the sensory centres of the cortex, analogous to that which, occurring in a motor centre, may produce cortical epilepsy; the one has abnormal sensation, and the other abnormal motion for its result.

3. This morbid irritation may either arise spontaneously, or it may be due to irritation in the peripheral organs of the senses, in the conducting nerves, in the sensory ganglia at the base, or in the white medullary conducting fibres; it may also be due to morbid activity commencing in the centres of ideation. In the first case the origin of hallucination is central; in the second, either peripheral or in the conducting media; in the third, it is intellectual; but in every case the sensory centre plays a most important part, for, if it be unaffected, no real hallucination can exist.

4. An illusion is merely a hallucination in which the morbid excitement of the sensory centre is due to a real impression received from without. The nervous impression, however, acting upon a nervous centre in a state of abnormal irritability, becomes transformed by it into a sensation other than the true one.

It is interesting to compare these theories with the contrary or, at least, negative conclusions, reached by M. E. M. Hartwell, of the Johns Hopkins University, an abstract of whose paper we quote from the *University Circular*. April, 1881:—

Apparitions, hallucinations and visions were held to be manifestations of pseudopia or false sight, due to lesion or disorder in some portion of the visual mechanism. It was the aim of the paper to show, through the discussion of the laws of normal vision, that the explanation of pseudopia is based upon the doctrine of reflex nervous action. Accordingly the nature of reflex action and its essential factors was first discussed. The physiology of sense organs in general, and of the visual organ in particular, was next considered; especial emphasis being laid upon the fact that sight is a function of certain centres or regions of the brain, rather than of the eye or of the optic nerve, which are respectively organs for the reception and transmission of visual stimuli. The antagonistic theories of Ferrier and Goltz regarding the localization of the functions of the brain were commented upon. The peculiar effects of certain drugs in producing visions were noted. Numerous cases of pseudopia were cited; and especial attention was called to those of Joan of Arc, Swedenborg, and of certain carefully recorded cases which occurred in the practice of the late Dr. E. H. Clarke, of Boston. The conclusion was reached that the visions seen by the victims of delirium tremens, emotional insanity, narcotic poisons and approaching death are attributable, chiefly, to disease or disturbance of centres in the brain; but that in the present state of science the precise localization of such centres is impossible.

The Italian professor has certainly gone much further, and with a plausible show of accuracy.

Simulation of Hallucinations.

The extraordinary power of simulation possessed by quite young and not at all intellectual children, is little appreciated by even medical men. A striking instance is detailed in the *Vierteljahrschrift für Gericht. Medicin*, Jan., 1881, by Dr. L. H. Ripping, director of an asylum on the Rhine. In April, 1877, it came to the knowledge of the authorities that Joseph G., a boy of 14 years, had excited great attention by his visions of the Virgin Mary and Jesus Christ. An officer was sent to the small village where he lived, and found about 800 persons collected in a field, many of them invalids, drawn thither by the fame of the vision and the miraculous power of the earth scooped out of a hole on the spot where the boy had seen the vision. They were praying and crossing themselves, and a woman, a butter dealer, was passing around the dirt collected from the hole.

Joseph G. was small in stature, of unhealthy appearance, the son of a poor peasant, but he could read and write fairly. He gave verbally and afterward wrote out, an account of how, on several occasions, the Mother of God and Christ appeared to him. He described her dress and repeated her words. When she agreed to appear at a specified hour, he would tell the neighbors, and hundreds would assemble to communicate with her through him.

He was taken and placed in the asylum of Dr. Ripping. At first it was thought that he was suffering under hallucinations and fanaticism, but after a most close and careful observation of his words and actions, when he did not think himself watched, it was conclusively shown that the young rascal was a thorough impostor, perfectly sound in mind but an adept in simulation.

As Dr. Ripping remarks, under other circumstances, we could easily have had, at this little Rhenish village, a repetition of the scenes of Lourdes, Knock, Marpingen, etc.

The Criterion of Hallucinations.

A very excellent essay on "The Philosophy of Sleep and Dreams," by Dr. Delboeuf, has been translated and published in the *Medical Press and Circular*. It is full of acute and thoughtful remarks. We quote what he says on the test question of distinguishing between an illusion (conception) and a reality (perception):—

By what characteristic can we practically distinguish a conception from a perception, when they both have the same brilliancy? The answer is very simple: The conception is altogether a personal matter; the perception is common to all. The engravings which are in my room everybody sees, everybody can touch; those which are in my imagination are inaccessible to all except myself.

In the matter, then, of perceptions and conceptions, the evidence of other men is the sole criterion to guide us. But this criterion unfortunately is not infallible. Does it not sometimes happen that entire populations see marvelous apparitions? In his instructive book, "On the Study of Nature," M. Houzeau, Director of the Observatory at Brussels, instances the sepulchral lamps deposited by the Romans in their tombs, which numerous witnesses declare that they saw still burning when the interior of the tombs was brought to light. Now, here is a thing perfectly impossible, and proved to be so. Then, again, what do we see in the descriptions, collected by Porta, of the opening of a Roman sepulchre in the island of Nisidia, near Naples? "Several sober, respected gentlemen, members of various professions," says M. Houzeau, "swear to having seen with their own eyes, and in the most positive and absolute manner, some chemical miracles, which were a perfect mystery to them." In the middle of the eighteenth century are certain miracles supported by a collection of proofs such as the best established historical events could scarcely show. In fine, what is stranger still, do we not in our own day see philosophers, *savants*, naturalists, such men as Fechner, Zöllner, and Wallace, allow themselves to be hoaxed by the spiritualistic jugglery of a Doctor Slade? * * * *

However carefully it may be considered, and however well weighed, we are always, of necessity, brought to this conclusion, which I have enunciated elsewhere, viz., that if on the one hand truth exists, on the other hand an absolute criterion of truth does not exist; that we must distinguish between subjective and objective certainty; that our convictions, however strong they may be, may be unfounded; that truth may have for us only an entirely provisional character. The sole motive which makes us reject a proposition resolves itself into the contradictions which it presents to other propositions considered by us as true. Then, as the number of these has always a tendency to increase, we have no guarantee that new contradictions will not some day arise; the history of the sciences has made us only too familiar with surprises of this kind.

This as he says, will no doubt be a grievous conclusion to many, as it is substantially denying the validity of any test, either subjective or objective, for truth; but the philosophical mind will not be shocked by a statement which most metaphysicians have long since recognized.

Epileptic Mania.

A highly important contribution to the medico-legal aspects of mental disease is made by Dr. James Finlayson, lecturer on clinical medicine in the Glasgow Western Infirmary, in the Glasgow *Medical Journal*, December, 1880. It is a paper illustrating the character of epileptic mania, and especially the fact that just as an epileptic fit may occasionally consist of the aura only, and nothing else—the fit being, as it were, aborted or suppressed—so, in other cases, we have the epileptic mania only, all the other phenomena of a typical attack being suppressed, or at least occurring in such an obscure form as not to be recognizable. He maintains, in fact, that epileptic mania, however, may occur without the least trace of anything corresponding to a convulsive fit, the explosion being, as it were, mental, instead of motor, in its character.

He observes:—

When such cases result in violence and murder, there is great unwillingness to admit that a person who goes through all sorts of purposive action, who procures suitable weapons, and uses them in a business-like way, can possibly be in a state comparable to that of an epileptic fit. The idea of loss of consciousness, so generally associated with the epileptic state, appears inconsistent with actions obviously purposive in character. It cannot, however, be too strongly insisted on that an elaborate series of actions, of a purposive character, may be carried out, although the true and higher consciousness of the individual is suppressed. When these purposive actions result in some terrible tragedy, and when the surroundings are such as to suggest motives for retaliation or revenge, it is difficult for lunacy experts to obtain a fair and impartial hearing; particularly is this the case in the present state of the administration of justice, which allows, and we may say, almost encourages, the calling of experts on both sides, as if they were special pleaders retained to support a foregone conclusion for the side on which they receive their fees.

Dr. Finlayson adds the details of several such cases, which seem to substantiate this assertion.

In immediate relation to the above should be mentioned an article by Dr. C. H. Hughes, of St. Louis, showing

Persistent Consciousness in Epilepsy,

published in the *Alienist and Neurologist*, April, 1881. Of several cases given we quote two:—

Eliza C., aged 12 years. Of late years she has had very pronounced epilepsy, the attacks of *grand mal* recurring about every fortnight, with frequent epileptoid seizures in the intervals.

This girl came under my medical care, February 1st, 1878, and, under vigorous treatment, speedily improved from a state of apparently helpless imbecility and untrustworthiness, after her paroxysms, to one of good average intelligence and reliability, so that the rest of her family could safely entrust her alone in the house, and permit her to go to school a part of each day. In the following August, after having been six months free from seizures, epileptoid paroxysms were displayed in evanescent attacks of psycho-motor paralysis, recurring every few days, of which the patient was wholly conscious, making "desperate" but fruitless mental efforts, "like one in a nightmare" (as she afterward stated), to overcome her momentary immobility of limbs and tongue, and attract attention.

Theo. B., aged 20, came under treatment in June of 1879, with *grand mal* without aura. His first seizure, in May, was caused by overwork in the harvest field, and mental depression resulting from failure to get pay for his work. He has been free from all manifestations of the disease since July, 1880; had a paroxysm of conscious automatism about the first, and a brief aphasic spell in the middle of September, 1880.

Dr. Hughes insists that this conscious condition is by no means rare, though it has not received the recognition it deserves, and he concludes his article with the following words:—

"Other clinical confirmations of epileptoid disease without unconsciousness have been recorded by us (*vide Alienist and Neurologist*, April, 1880), and others still might be here enumerated from our own experience, but the testimony would be needlessly cumulative. The recognized and conceded automatism of certain undoubted epileptics, in which there is every appearance of a consciousness sometimes, though exceptionally, quite complete, coupled with a psycho-motor excitation and consequent impulsion to travel or perform accustomed, as well as unaccustomed journeys and acts, should, even without the proofs here given, dispel that incredulity which has led some to deny the possibility of consciousness in epileptic states. The idea of unvarying loss of consciousness should take its place with that ancient and exploded, but once thoroughly accredited fallacy, which gave to this malady the name of *morbus sacer*."

Another important feature of the epileptic condition, is the opposite condition, of

Cerebral Trance,

or unconscious intelligent action. Such a case is recorded by Dr. T. L. Wright, of Bellefontaine, Ohio, in the Cincinnati *Lancet and Clinic*, Jan. 29th, the subject being a clergyman of learning and ability, some years before subject to epileptiform seizures, with prolonged unconsciousness.

He writes:—

The facts in my *singular experience*, of which you make inquiry, are, so nearly as I can recollect, about the following:—

1st. I wrote and preached a sermon from a very familiar text, and in two weeks afterwards wrote and preached a second sermon from the same text, *without any recollection of the first*, only reminded of the first when I went to put away the second in a drawer kept for my sermons, where I had put the first one two weeks previous.

2d. It was immediately after a severe "spell," of several weeks, of "*general debility*," and before I had entirely recovered, and during which sickness I was "flighty" most of the time.

3d. The second sermon was a considerable improvement on the first, as I saw from the comparison of the two manuscripts.

Dr. Wright makes the following judicious observations on this case, and its application to forensic medicine:—

In cases of criminal prosecution, where mental defect is set up in defence, it has been a custom to claim that if epilepsy, once present, had disappeared for a considerable period of time, that fact goes to show that the mental state had become sound, and that in such a case the defence of insanity is not valid. *The exact opposite* is the correct assumption; namely, if epilepsy has disappeared, the presumption is very strong that some other neurotic state has been substituted for it; and the probability of an unsound mental condition is *increased* by the absence of the epilepsy. For it is becoming established that, in all those cases of unstable equipoise among the nerve centres *which are inherited*, or are *constitutional*, there is no hope of a final equilibrium being established.

As epileptic attacks are often feigned by criminals, a pathognomonic sign for the

Detection of Feigned Epilepsy

is of general interest. Such a one is mentioned by Dr. M. G. Echeverria, a well known authority on this disease, in the *American Journal of Insanity*, January, 1881, not, indeed, as a new discovery, but not very generally known. He says:—

Attentive examination of the pupils of an epileptic after seizures of *petit mal* or *grand mal*, discloses an alternate dilatation and contraction of the iris, persisting for over a minute after the patient's return to consciousness. This epileptic pupil is also conspicuous during the paroxysms of mania, at those moments when the patient suddenly becomes stupefied for a few seconds, staring with eyes wide open and fixed; it again betrays the dubious forms of psychical epilepsy, and, above all, furnishes, even to those most inexperienced with the malady, a sure means of differentiating, in a ready and easy way, true from feigned attacks. Again, if we cover with a handkerchief or towel the nostrils and mouth of an epileptic, at the moment he is seized with a fit, this continues without change, because the obstacle thus put to breathing does not materially interfere with the asphyxia characteristic of the initial stage of the convulsive paroxysm, upon

tonic contraction of the thoracic muscles. This process, on the contrary, at once determines in the simulator a *besoin de respirer*, with inevitable suffocation and struggles, which discloses the best studied imposture. It happens, however, with certain cases, and mainly in incomplete seizures, that the impediment to respiration quickly suspends them, but then, a phenomenon impossible to simulate always takes place, demonstrating in a no less positive manner the real nature of the attacks. This phenomenon is, once more, the convulsive contraction and dilatation of the iris, or the epileptic pupil, which, as already stated, may recur for more than a minute before it entirely disappears, and which becomes very remarkable when the eye is exposed to a bright light.

Correspondence.

A Case of Dystocia—Relief by Episiotomy.

Ed. Med. and Surg. Reporter:—

Labor may be rendered difficult by many and various causes. They are generally arranged into two classes. Those which render labor difficult by causes referable to the mother, and those in which the child is at fault.

The following case of difficult labor is one which belongs partly to both classes; where the labor was made difficult, on the part of the child, by an unusual large, healthy head; and on the part of the mother, by a small vulva.

The patient, a young married lady, twenty six years of age, primiparæ, had engaged, and was attended by Dr. Wm. M. Caterson. The Doctor was sent for about ten P.M., Sunday, April 3d. The patient stated to him that the pains came on Saturday evening. They were sharp cutting pains, referred to the uterus, coming and going every twenty minutes, keeping her awake all the night. Sunday she continued to have them from time to time, not as often as before. In the evening they again became worse, and when the doctor arrived she was having them about every five minutes.

The doctor remained all night with her, and part of next day, very little progress being made during that time, and not wishing to bear the entire responsibility, he desired a consultation with me, which was granted.

I was called about five P.M., on Monday. At my first visit I found the patient in bed. Upon questioning her I obtained the following information: This was her first pregnancy; thought she was two weeks before her time. She was in labor forty-eight hours. The pains during my stay were feeble and slow, but severe enough to keep her almost in continual suffering. In making an examination *per vaginam*, I found the head presenting at superior strait, second position of vertex. Os dilated to about two inches in diameter. Membranes intact. Fæces in rectum could be felt through posterior wall of vagina. Abdomen considerably enlarged.

Patient was told there was no occasion, at present, for alarm. She was ordered fifteen grains of quinine as a uterine stimulant, and an enema of soap and water. I left, and promised to return later in the evening.

I saw her again at half-past eight P.M., when the doctor informed me that about one hour after taking the quinine the pains became more severe, lasting longer and more effective. The os was dilated to about three inches in diameter. Presenting part engaged in pelvis. Rectum empty.

At my next visit, 10.45 P.M., I was told that the membranes had just ruptured. Pains were of a bearing-down character. Os fully dilated. Large head diagnosed. Patient had vomited during my absence; she was ordered seven grains more of quinine. The head slowly descended to the perineum. From the rupture of membranes to the appearance of head at vulva four and three-fourths hours elapsed. During this time the pains were strong and severe. When the head was low down, and the perineum distended to its utmost, it was evident the head could never be born without a rupture, owing to the smallness of the orifice of vulva. I tried to save perineum by endeavoring to deliver head during the absence of pains, as taught by Prof. R. A. F. Penrose. The head could not be born, as the vulva was too small, rigid, and inelastic.

The application of forceps was considered, but the danger of rupture by their use was evident.

I obtained consent of the patient to perform episiotomy. This I did with a pair of scissors, making a cut on each side of the vulva, about one and a half inches from median line of perineum. This procedure removed the tension of vulva, and allowed the head to pass out readily, saving, at the same time, the perineum, the fourchette, even, not being torn. Passing my hand around the neck, I discovered the cord encircling it. This was easily slipped over head. The shoulders and body were delivered without any difficulty.

The child was an unusually large and well developed one; the head being particularly large. Smacking the child with the hand was all that was necessary to establish respiration.

The cord was cut, and placenta delivered by Crede's method. No stitches were applied to cuts, the wounds healing by granulations. There was no hemorrhage from the incisions nor from the uterus.

Child born 3½ A.M., Tuesday, April 5th.

Duration of Labor.—1st stage. Dilatation of os, 53 hours. 2d stage. Expulsion, 4¾ hours. 3d stage. Delivery of placenta, 15 minutes. Total 58 hours.

Weight and Measurements of Child.—Weight, 12½ pounds. Length, from vertex to buttocks, 15½ inches; from buttocks to soles of feet, 10 inches. Entire length 25½ inches.

Circumference of Head.—Tape passed from occipital ridge above ears to frontal bones, 15¼ inches.

Diameters of Head.—Bi-parietal, 4 inches; occipito-mental, 6 inches; fronto-mental, 4 inches; occipito frontal, 5 inches; bis acromion, 5 inches; bis iliac, 4 inches.

The cause of this lingering labor was, I believe, the excessive distention of the uterine cavity by the large foetus. Just the same as we have in dropsy of the amnios, where the uterine walls are over-distended, making them thinner and preventing them from acting with energy.

In primiparæ, delivering the head during the absence of pain will, in the majority of cases, save the perineum from rupture. Where this cannot be done, cutting the vulva, as in this case, is the only resort. The edges can be united by a stitch. None were used in this case. No deformity followed.

I would say, in conclusion, that the action of quinine in this case, as a uterine stimulant, was a very decided one. I have seen it used in similar cases, and always with a very happy effect. I consider it, in full doses (15 gr.), a very valuable aid in cases where the pains are inefficient. Its mode of action is not yet fully understood. It is believed, however, that it does not originate uterine contractions, merely stimulating those present.

The lying in of the patient was not attended with anything unusual. Mother and child are both well. FRANK O. NAGLE, M.D.

1439 *North Fifth St., Philad'a.*

Static Electro-Therapeutics.

ED. MED. AND SURG. REPORTER:—

My paper on "Static Electricity in Therapeutics," of March 12th, was followed by others in another journal, in which the Holtz machine was advocated, with double or quadruple plates, the object being to gain *quantity*, and to overcome the defective or absolute refusal to work in damp weather. Its inclosure in a glass case was proposed, with the employment of a vessel therein, containing sulphuric acid or other substance, to absorb the aqueous vapor or dry the air immediately surrounding the machine. Aside from the unnecessary complication of multiplied plates, with the accompanying difficulties in adjustment, which can be avoided, and the desired result attained, by simply increasing the diameter of the plates in the single machine, the dehydrating experiment has been tried long ago, in a variety of styles, and it has invariably failed. The simple truth is that no Holtz machine will work *satisfactorily* in bad weather, if at all, and the modifications proposed only add to the perplexity of its owner, should he be (as is often the case), unskilled in mechanics. To illustrate this point practically, I know of one instance in which a gentleman invested a large sum in a quadruple machine, and it has failed, except in dry atmospheric conditions, when any low-priced or home-made apparatus would act.

That the "Tœpler" is reliable at all times has been proven to my own satisfaction, particularly during the decidedly unfavorable weather of the last ten days, when other static machines were dead, so far as results were concerned.

The endorsement of such eminent gentlemen as Professors Barker, Bartholow, and teachers of physics in our leading scientific institutions, is alone sufficient to attest the reliability of the new machine, and when it is capable of producing maximum effects in a room filled with students (a good test), it will undoubtedly act in the dry air of the consulting room, not contaminated by exhalation from a large audience.

Since my article appeared, several improvements have been made to the "Tœpler," and as it is impossible for me to answer separately the numerous letters received, asking for information, I impose upon your widely circulated journal as a ready means of reply. The No. 1 machine is too small for therapeutic work, but either the Nos. 2, 3, or 4, are adapted to the wants of the practitioner. A couple of Leyden jars (pint and quart), with an insulated ball electrode, an insulated platform large enough to sustain a chair, which may be home-made, and three yards of small brass chain, are all that is needed. Static electricity possesses all the value of Faradic currents, with properties "*per se*" which space does not now permit enlarging upon, and I am daily convinced of its value and ultimate appreciation by those who devote study to scientific electro therapeutics.

WM. R. D. BLACKWOOD, M.D.

Philadelphia, May 27th, 1881.

A Correction.

ED. MED. AND SURG. REPORTER:—

In your journal of May 28th, on page 597, I find, under the heading "Medical Societies," and in the section devoted to a report of a paper read by Dr. David Price, of West Chester, the following:—

"Dr. Sutton, of Pittsburg, not only disputed the soundness of Dr. Price's treatment, but declared it to be based upon false pathology, exploded hundreds of years ago, and revived again recently," etc.

This statement is incorrect: what I said was, that the pathology was false, meaning that it was erroneous, and if my discussion of it was not effective, why did Dr. Price amend the title of his paper after the discussion, so as to make it read, "The Importance of Local Treatment in Congestion and Inflammation of the Cervix of the Impregnated Uterus?" *The title of the paper as read*, was: "The Importance of Local Treatment in Inflammation of the Cervix of the Impregnated Uterus."

The word *Congestion* was the result of my remarks, in which I disputed the existence of inflammation, but held that the condition was *Congestion.* R. S. SUTTON, M.D.

Pittsburg, Pa.

Maternal Impressions.

ED. MED. AND SURG. REPORTER:—

Your article, "Maternal Impressions," which I have just read, reminds me of a case in point that came under my observation last year. I was called to see a patient, and while prescribing, observed a child about two years old who had lost a leg, which, to all appearance, had been amputated about the middle of the os femoris. The leg, muscles and *bone*, were well developed to the point of amputation. The stump was smooth, round, and of the apple-dumpling type, a little puckered at one side, with a tit-like attachment resembling a supernumerary toe. Upon inquiry I found it to have been congenital. The mother *affirming* the amputation—or arrested development—to have been produced during ges-

tation, by a fright which she received from a *one legged* man. If this was not the result of a maternal impression, it was, at least, a very extraordinary coincidence.

NEWS AND MISCELLANY.

The "Hammond Prize" of the American Neurological Association.

The American Neurological Association offers a prize of five hundred dollars, to be known as the "William A. Hammond Prize," and to be awarded at the meeting in June, 1882, to the author of the best essay on the *Functions of the Thalamus in Man.*

The conditions under which this prize is to be awarded are as follows:—

1. The prize is open to competitors of all nationalities.

2. The essays are to be based upon original observations and experiments on man and the lower animals.

3. The competing essays must be written in the English, French or German language; if in the last, the manuscript is to be in the Italian handwriting.

4. Essays are to be sent (postage prepaid) to the Secretary of the Prize Committee, Dr. E. C. Seguin, 41 West 20th street, New York city, on or before February 1st, 1882; each essay to be marked by a distinctive device or motto, and accompanied by a sealed envelope bearing the same device or motto, and containing the author's visiting card.

5. The successful essay will be the property of the Association, which will assume the care of its publication.

6. Any intimation tending to reveal the authorship of any of the essays submitted, whether directly or indirectly conveyed to the Committee or to any member thereof, shall exclude the essay from competition.

7. The award of the prize will be announced by the undersigned Committee, and will be publicly declared by the President of the Association at the meeting in June, 1882.

8. The amount of the prize will be given to the successful competitor in gold coin of the United States, or, if he prefer it, in the shape of a gold medal bearing a suitable device and inscription.

SIGNED, F. T. MILES, M.D., *Baltimore.*
J. S. JEWELL, M.D., *Chicago.*
E. C. SEGUIN, M.D., *New York.*

A Strange Story from Colorado.

The *Pittsburg Medical Journal*, for April, has an article not calculated to improve the reputation of Colorado as a health resort. It is to the effect that the high altitudes there materially decrease and often destroy all sexual desire and power in men; and what is yet more curious, that the altitude or climate has the reverse effect on women. It adds that a vigorous man "may live for years there, and never, either sleeping or waking, will he have the least sexual desire;" "nor can the combined influences of wine and women arouse the dormant passions."

Such a statement is too extraordinary to be allowed to pass unnoticed by our Colorado brethren.

Improvement in Ovariotomy Statistics.

In his last 137 cases of ovariotomy Mr. Spencer Wells has reduced the mortality to less than ten per cent. Keith has recorded fifty consecutive cases, with only one death. This vast improvement is chiefly owing to the most rigid antiseptic precautions.

American Neurological Association.

The seventh annual meeting of the American Neurological Association will be held in New York on June 15th, 16th and 17th, at the Academy of Medicine. No. 12 West 31st street. The profession are invited to attend.

Items.

—The Countess Wilhelmina Huguay recently took the degree of Doctor of Medicine, in the University of Zurich. She is a Hungarian lady.

—Following a stupid and most injurious precedent, the Turkish government has forbidden the local newspapers in that country to say anything about the plague, correct or incorrect. That is better, however, than some city Boards of Health we have heard of in the United States, who systematically lied about epidemics prevalent in their municipalities.

—A discussion is going on in various English medical journals, as to whether beer or ale shall be given as part of the regular ration in hospitals and asylums. To an American it seems absurd to debate such a question. We do not believe there is a single hospital or asylum in the United States in which beer or ale, or any form of alcoholic beverage, is issued as an article of ordinary diet.

QUERIES AND REPLIES.

Chronic Colitis.

MR. EDITOR.—A chronic case of colitis (two years' duration), came under my care about six months ago. There are about half a dozen stools every day, partly blood. The remedies usually successful in similar cases, to wit—cupri sulph., argent. nitras, ox. zinc, subnit. bismuth, spts turpentine, etc., have been of little benefit. Can any one suggest anything else that has been useful in their hands in like cases? WM. H. C., *Ills.*

Pododynia.

MR. EDITOR.—Will any reader of the REPORTER, who has had experience in the treatment of pododynia, give me his views of pathology and treatment. I have a young man of rheumatic diathesis, æt. twenty-one, who has been suffering, as Prof. Gross describes under the above name, for two years. Last attack of rheumatism was six or eight years ago. Have tried, in the treatment of his case, the silicates, iodide potash, bi-chloride hyd. vest, gum bandage, elevation of feet, and have him now on Donovan's solution and a constant repetition of blisters. I solicit the views of experienced gentlemen. Respectfully, W. H. J.

PARIS EXPOSITION, 1878.

We take pleasure in stating that we were awarded a

SILVER MEDAL

FOR OUR EXHIBIT OF

SOLUBLE-COATED PILLS

AT THE

Universal Exposition, Paris, 1878.

This being the *only Silver Medal* (the HIGHEST RECOMPENSE awarded to Pills), is conclusive evidence as to the superior merits of our Soluble-Coated Pills, as compared with all other kinds and justifies the claims we have always made for the excellence of our manufactures.

Sold by all druggists.

QUINQUINIA.

(NOTE.—"Quinquinia" is derived from the French term for Cinchona Bark, "*Quinquina.*")

The preparation consists simply of the Alkaloids of Cinchona Bark in the form of a light-brown precipitate. Being a natural combination, the proportions of each constituent may vary somewhat, according to the bark used, but after repeated examinations, the average composition is determined as follows:—

Quinia Alkaloid,	15 per cent.	C	H	N	O
Quinidia do	15 "	20	24	2	2
Cinchonidia do	15 "	C	H	N	O
Cinchonia do	15 "	20	24	2	
Chinoidine Purified,	30 "				

From experience, it has been determined that the dose of Quinquinia should never exceed that of Sulphate Quinia. Being in the alkaloidal state, it is consequently more efficient than if a sulphate.

To meet the general desire for an efficient Antiperiodic and Tonic, at a moderate price, QUINQUINIA is offered at $1 per ounce.

Sample ounces by mail, $1.10 per oz.

Specimens for trial, without charge, furnished physicians who kindly mention MEDICAL AND SURGICAL REPORTER.

TESTIMONIAL.

During a large part of the year, the great majority of the patients of the University Dispensary have more or less malarial trouble. The faculty have tried nearly every one of the cheaper substitutes for Quinine, and have settled down upon Quinquinia as the one from which best results are obtained. I always specify it where my cases need anti-malarial treatment.

Original Department.

Lecture.

ON THE NECESSITY AND USE OF THE SUSPENSORY BANDAGE IN VARIOUS AFFECTIONS OF THE TESTICLE, ESPECIALLY THOSE OF A VENEREAL NATURE.

BY F. R. STURGIS, M.D.,

Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York: Surgeon to Charity Hospital, B. I., etc., etc.

Gentlemen—My apology for devoting a lecture to the suspensory bandage is its almost universal use, from its necessity as a preventive to injury and weakening of the genitals, and the by no means infrequent bad results which follow from an ill-fitting or improper bandage.

The three points I shall consider are:—

1st. The diseases for which it is applicable.

2d. The evil results which follow the use of a bad bandage, and the bandages best adapted for use.

The diseases of the testicle in which the bandage becomes a *sine quâ non* in treatment, are gonorrhœal epididymitis, varicocele, and neuralgia of the testicle. And first, as to the gonorrhœal testicle: This affection, as you know, does not come on at the first access of the disease, but is delayed until the twenty-third to the twenty-fifth day, and although induced by the extension of inflammation to the membrane lining the cord and testis, may yet be averted, by appropriate appliances. The first and foremost of these is support.

The object of this support is twofold: first, to prevent stasis of blood in and congestion of the organ, and second, to relieve the nervous tension and aching of the cord. The best support is the hand, but as the hand can do more service in other ways than by supporting the testicle, artificial aids are called into play, which are all of more or less good. In gonorrhœa the ounce of prevention is worth the pound of cure, hence the point which I have already laid stress upon—to direct your patient to obtain a well-fitting suspensory bandage at the commencement of the disease, assuring him that if he does not do so he runs a risk of suffering from a painful and tedious complication.

In varicocele the necessity is still more apparent, for the swollen and congested veins are a standing warning for support, and the discomfort and aching are continually appealing to the patient's nervous system, so that here a twofold condition is induced, physical organic changes in the veins and nervous irritability, a condition of things which sometimes leads to atrophy of the testis.

Neuralgia of the testis is another disease which is often alleviated by support, and if to that be added some degree of compression, such an amount of ease and comfort is obtained, compared to the former mal-aise and torture, as to make the patient feel the value of a proper apparatus for the purpose. This compression should never be delegated to the bandage, whose sole function is to support the testis and to assist the scrotum, but it should be obtained by other means. The best thing for the purpose is several coatings of a flexible collodion, which, upon evaporation of the ether, contracts and produces a steady, even, bearable pressure over the neuralgic testicle.

These three affections are the most important

ones for the application of the bandage; but besides this, many a man in health is benefited by the use of a well adjusted suspensory bandage. Stout persons, in whom the abdominal viscera, loaded with fat, press heavily against the abdominal rings, and by pressure impede the circulation of the cord, are cases in point, and so much comfort do they get, that they never leave off their suspensory bandage. In summer, during the warm weather, the heat will often induce a temporary varicocele, which is relieved by a simple and proper support. Hence, you see, not only in disease, but in health as well, a support to the testicle is needed, and it behooves you, as surgeons, to be able to advise when and in what cases a bandage is requisite.

But to be of service it must fit well. What, then, are the requisites of a good bandage? They are two: support from below upward, and no cutting nor undue pressure upon any portion of the genital apparatus. Many varieties of bandage are sold, but nearly all are wofully defective, the most serious fault being that they either cut or exercise undue pressure at the perineo-scrotal angle, or else they abrade the skin at the junction of the scrotum and the thighs.

The best bandage is the one I show you, and is sold in the shops under the name of Rawson's United States Army Suspensory Bandage. In the first place, the elastic girdle admits of a self-adjustment to the shape of the patient's body, and to the varying positions which it may assume; in the second place, the posterior edge of the bag being cut in a sloping direction does not injure the scrotum nor the perineum, but lies evenly and snugly; and finally, the thigh straps are a good feature in securing steadiness, and in preventing the scrotum from sliding out of the bag, as it is so apt to do in the cheap and common bandages.

Before closing this lecture, I wish to say a few words about some of the evils which result from a poor or ill-fitting bandage. About those which do not retain the testicle, from the shallowness of the bag, I suppose it is not necessary to say much, still less to advise you against them. There is one seriously bad result that I have seen from a poor bandage, viz.: a perineal abscess, due to compression and irritation from the thick and clumsy edge of the bag; and I have seen several cases where a deep-seated urethral discharge was kept up by the same cause. Hence it is that I have devoted a lecture to this subject, hoping that by calling your attention to the dangers you will avoid them.

Communications.

A CONTRIBUTION TO THE STUDY OF NERVOUS DISEASES.

BY EDWARD C. MANN, M.D.,

Physician-in-Chief to Sunnyside Retreat for Diseases of the Nervous System, Dipsomania and Opium Habit, Tarrytown on-the-Hudson, N. Y.

Somnambulism.

The partial interference with sensibility and mobility, and the consequent limitation of will in somnambulism, is known rather as a physiological curiosity than as an affection which places the individual in a different mental and legal position.

In whatever these intercurrent spaces of non-existence may have originated, whether from unfettered determination, or the idle, wandering imagination, or from the brain wasting following moral or intellectual hard work, it is certain that occasionally they pass beyond the power and in defiance of the will, and should be classed under the head of morbid nervous affections, if not with actual mental disorder.

A majority of the states similar to somnambulism and allied to it, such as trance and trance-coma, absence of mind and obliviousness, are probably produced by narrowing the scope of intellectual exercise, by nullifying the influence of the emotions, or by contracting the mental forces, which induce ill health, both by giving disproportioned prominence to certain faculties, and allowing others to fall into desuetude and apathy, and probably producing undue or defective nutrition in certain parts of the brain.

A very remarkable instance of forgetfulness and absence of mind occurred in a poet, who had taxed attention and introspection to the utmost, and who, having confined the exercise of intellect and memory within a narrow range, had impaired the observant powers. The anecdote occurs in the biography of Horkham Fréré, the scholar and man of letters, who, handing the Countess of Errol to supper, drank the negus he had prepared for her, and altogether forgot the object of their visit to the dining-room; and who, on the day of his marriage with the same lady, had no recollection until the evening that he had promised to accompany his bride to the country—having occupied the intervening time in reading his poems to his publishers. It is also related of Sir Joshua Reynolds, that after he had been for hours occupied in painting, and walked out into the street, the lamp posts seemed to him to be trees and the men and women moving shrubs. He had fixed his attention for such a length of

time on the picture before him that he could not direct it to other objects of sensation. It is noticeable that nearly all of these instances occur in men of vigorous, acute, perceptive minds, and of lofty intellect. It is the peculiarity of all these states—when they are not merely temporary effects of stimuli—that they essentially result in such consequences of bodily or mental degeneration as, robbing the thinking part of our nature of its nobler endowments, leave it in the impoverishment of an appetite, an unvarying set of words, a peculiarity, or a single, all-embracing thought; the morbid element consists chiefly in fixedness, in the inability of the will to substitute another train of reflection or perception.

The will, though feeble and fickle, is not entirely extinct, as it serves to guide in the direction of the predominating, if not constantly permanent, notion or incentive. It seems to me that we must class such states in the same category as the preoccupation of the insane, whose disordered imaginations can admit of nothing but the present and ruling impulse, the absorbing and exclusive anguish of the melancholiac. In all these cases there exists, in different degrees, a suspension of consciousness.

These spaces of non-existence, which sometimes occur at different ages and under widely different circumstances, and which pass beyond the power of the will, are states of actual disease of the nervous system, and are on the border-land which divides sanity from insanity. As I have just remarked, men of lofty intellect and vigorous and acute minds, by excessive and continuous application, overtaxing their attention and introspection, and confining the exercise of their intellect and memory within a narrow range, weaken their observant powers, and by concentrating their minds upon particular objects produce grave disorders of the nervous system. Sir Isaac Newton is a prominent example of contemplation so intense as to render him entirely oblivious to self and surroundings, or to the disturbances of perception. As regards their mental and legal responsibility, neither Sir Joshua Reynolds nor Sir Isaac Newton, during their states of partial suspension of consciousness, would have had a knowledge of the nature of their acts, whether they were culpable or blameless. It is a psychological fact that after the attention has been for a great while intensely fixed upon particular objects, the person cannot direct it at will to *other* objects of sensation. The morbid states of the brain which may be induced are exemplified in a marked degree in the lives of ascetics and ecstatics, and in those whose intense devotional feelings, as in the "Convulsionaries," Brahmins, etc., extend temporarily to enfeeblement of volition, and where the diseased functions of motivity and sensibility manifest themselves by violent convulsions and complete anæsthesia.

Somnambulism is a morbidly profound sleep, in which "the sceptre of reason is surrendered to a physical directed fancy." It is due, probably, either to an overloaded stomach pressing on the solar plexus, producing a partial paralysis in the coats of the arteries, and so in the cerebral circulation; sleeping with the head too low, strong mental emotion, etc., and it is a peculiarity of somnambulism, that even after the removal of the cause, the habit once established is apt to remain. It is frequent in youth and about the age of puberty. In states of unconsciousness accompanying somnambulism, the senses are awake and preternaturally alive. The muscles are regulated, and regulated, too, with a wonderful precision and power. There is a purpose, and there is a coördination of acts for its accomplishment; but consciousness is still asleep, and memory retains no record of the transaction, although it may have been prejudicial in the highest degree to the interest of the actor, or of others. In many states of unconsciousness the mind is forced to think or feel in a particular way, and is forced to instigate certain deeds in flagrant opposition to its ordinary character and tendencies, and in utter disregard of the promptings or of the resistance of other motives and considerations. There is a very close relation between acts committed during states of unconsciousness and mania transitoria, epileptic paroxysms, and irresistible impulses of insanity. They have in common irresistibility, suddenness, and rapidity. They are alike unannounced and of short duration. They are alike characterized by the exercise of free will being fettered or perverted, and there are undoubtedly distinct morbid conditions in all these different states. If we examined cases with sufficient care, in which states of unconsciousness occur, I feel quite sure we should discover prodromic signs of either exalted sensibility, suffering, sleeplessness, vague sensations which could not be defined, and other indications which have been observed to usher in other species of the neuroses. Somnambulism may be hereditary, but it is not inconsistent with fair health. It is apt to become periodical, patient having attacks once a week, fortnight, or month.

The treatment of somnambulism consists in preventing the very deep sleep in which the

phenomena of somnambulism are exhibited. The patient should be awakened once or twice each night, before the phenomena begin to appear; soon after retiring, and again after four or five hours' sleep, will usually answer.

Patients should dine in the middle of the day, and while taking care that all meals should be light and digestible, should be particularly careful not to overload the stomach at night. The use of electricity and nerve tonics, to bring up the general health to the highest point, are indicated.

Friends should be cautioned not to awaken patient when walking, as the fright may act prejudicially. He should be quietly put back to bed. The head should be well propped up by pillows, and too great weight of clothes must be avoided.

Catalepsy

Is a disease of central innervation of the nervous system, and may be accompanied by or accompany many forms of insanity.

In a cataleptic paroxysm the limbs of a patient remain in the position in which the patient had them before the inception of the paroxysm, or in which any bystander may place them during the paroxysm.

The patient's will is powerless to bring the limbs into any other position, by reason of muscular contraction induced by excitement of the motor nerves proceeding from the spinal cord.

Catalepsy accompanies many of the neuroses, such as insanity and chorea, and is induced, probably, by mental emotion.

It is preceded by dizziness, headache, and a very irritable state of the general nervous system, and begins very suddenly.

A patient sitting at my dinner table, who had placed herself under my care, presented the following typical symptoms and manifestations of a cataleptic attack, which serve very well to illustrate the disease as it generally appears. The lady in question, while in the act of conveying a morsel of food to her mouth, became suddenly rigid and pale, the arm being arrested in its passage, and being immovably fixed with the fork a few inches from the mouth. The whole body was as motionless as if the patient were carved out of stone. The eyes presented a widely opened, staring condition, and consciousness and sensibility were entirely suspended. Respiration could not be detected, and the pulse wave could not be felt at all. In about four minutes the patient sighed deeply, made a full inspiration and resumed her dinner, quite unaware of what had happened to her. Patients sometimes retain full consciousness during an attack. These cases are of interest to the practitioner, although comparatively rare, as the cataleptic paroxysm or fit annoys and disturbs the patient's mind, lest they should come on while traveling or away from home and friends. Although the fits generally last but a few minutes, they may, possibly, last for several hours, and in extreme instances may last for days. The chief indications for treatment are to improve the general nervous tone by nerve tonics and electricity; induce the patient to lead an outdoor life, eat regularly, avoid rich, indigestible food; to retire early; and if the patient complain of a sleepless condition, to administer the bromide of lithium, in five-grain doses, at bedtime, or the Fothergill's solution of hydrobromic acid, in fifteen to thirty-drop doses, in water. I have found the constant current the most serviceable, under the form of central galvanization.

To recapitulate: catalepsy comes on suddenly, generally after mental or emotional disturbances; the patient becomes corpse-like and pale, the respiration being slow and the pulse very soft, and, perhaps, not discernible. The patient cannot be roused and sensibility is lost.

The stiffness of the muscles is a diagnostic feature of the disease, which is such that, if a limb be put forcibly into any position it retains it.

Patients remember nothing of any attack or what transpires during its continuance.

TWO CASES OF COMPOUND GANGLION OF THE FLEXORS OF THE HAND, AND THE TREATMENT.

BY J. S. WIGHT, M.D.,
Professor of Surgery at the Long Island College Hospital.

Reported for the MEDICAL AND SURGICAL REPORTER.

CASE 1.—Mr. W. W., age 38 years, foreman in a warehouse, married, born in England, a patient of mine for many years, had a large compound *ganglion* on the anterior aspect of the left hand, wrist and forearm, which began about four years previous. He did not wish to leave his work, for the purpose of having an operation, in order to make a radical cure. The swelling in the palm of the hand and above the wrist joint finally became so great as to seriously impair the use of the hand. At this time, May 1st, 1879, I advised an operation, which was postponed, on account of the temporary indisposition of the patient.

During the last week of the following June the ganglion began to inflame, becoming red,

tense, and painful. In about ten days the tissues in the palm of the hand became quite thin, as if there was an abscess *pointing* at the most prominent part of the ganglion. At this time an opening was made at the point where the tissues were thinnest, by means of a narrow curved bistoury, so as to allow the contents of the ganglion to flow away slowly. The contents were a healthy pus, the ganglion fluid and some fibroid bodies. The hand was dressed with lint, saturated with carbolized oil; the same dressing being continued during the subsequent treatment. The hand and forearm were gently compressed with a bandage, which was removed and reapplied from day to day—a compress being kept on the part above the wrist, where the ganglion had been prominent before the operation. The sac of the ganglion slowly contracted, and formed less and less purulent fluid from day to day during the four or five subsequent weeks, and finally became entirely obliterated, and the opening in the palm of the hand very completely cicatrized.

From the time of the operation till the end of treatment, every time the hand was dressed passive motion was made. Each and every finger was moved, so as to prevent adhesion of the flexor tendons, and so as to remove the persistent flexion that had been caused by the ganglion. The result was quite perfect: the motion and the strength of the hand, wrist and forearm were, according to the statement of the patient, as good as they had been previous to the formation of the ganglion. A very small scar can be seen in the palm of the hand, where the opening was made.

Case 2.—Miss D. D., age 20 years, servant, born in Ireland, had a large compound *ganglion* on the anterior aspect of right hand, wrist and forearm, which began about three years previous. She had always been well. The ganglion was painful in the morning, and interfered with her work.

This patient was admitted to the Long Island College Hospital, the second week in February, 1881. On the 9th of February I performed an operation, which may be described as follows: After the administration of ether, the hand, wrist and forearm were placed under the antiseptic spray, a puncture by an ordinary tenotome was made into the cavity of the ganglion, at the most prominent points, both above and below the annular ligament, the small nozzle of a Davidson's syringe was inserted into the upper opening, and the ganglion was completely washed out with a ten per cent. solution of carbolic acid—carrying out a large number of fibroid bodies: The fluid of the ganglion would probably measure about six ounces. An antiseptic compress was laid on the anterior part of the wrist, over the entire sac of the ganglion, and kept firmly in place by a bandage. In about one week the bandage and compress were removed and reapplied; soon after, the ganglion began to fill again, and after it filled up full and tense, it began slowly to diminish in size; the sac slowly contracting and the fluid being absorbed.

On the 30th of March the patient was given ether, and I again opened the ganglion sac above the annular ligament. The sac was very much thickened, it was firm and resisting, about one-half of an ounce of fluid came out and a few fibroid bodies. The motions of the fingers and wrist have become much more extensive. A pad of carbolized oakum was bound over the opening.

Passive motion of the joints and tendons of the hand and forearm was made from day to day, and compression of the tumor continued. On the 7th of April the swelling in the palm of hand was almost gone, and a fleshy swelling was left above the wrist, mostly made up of the contracted and closed sac of the ganglion. The motions of the parts, both active and passive, were approaching the normal.

The patient was discharged from the hospital on the 4th of May, having good use of her hand, there being still some swelling above the wrist, though the sac appeared to be obliterated.

THE DIAGNOSIS OF MORBUS BRIGHTI FROM OPHTHALMOSCOPIC SYMPTOMS IN THE RETINA OF THE NEGRO.

BY W. H. WYNNE, M.D.,
Of Kansas City, Mo.

As the diagnosis of the exanthema in the negro is difficult and the symptoms referable to parts other than the skin, it is equally difficult to state positively the exact condition of cases of disease of the retina from ophthalmoscopic symptoms.

While a student in the immense clinic of the Ophthalmic and Aural Hospital, of New York city, but few cases of retinal disease in the negro presented themselves. It is stated in text books, and I have heard it stated by men of good reputation, that the retina shows itself in the eye of the negro by a "gauze-like" or "spider web" appearance, veiling the fundus. I have examined, at every opportunity, the retina of the eye of the negro, the cases now numbering one

hundred and nine, and I have yet to see, in what might truthfully be called the healthy condition, any such appearance. The ophthalmoscopic picture, as I have invariably seen it, is as follows, and I regard, from close examination of a large number of retinæ in the negro, the "gauze-like" or "spider web" appearance as false, and a statement repeated by men who have heard their superiors repeat it, who have themselves in turn learned it in precisely the same way.

Here are the facts as I see them: instead of the reddish reflex of the white, the reflex in the black is almost the same as that of detached retina in the white, or like the localized cloudy appearance produced in the retina from embolism of a branch of the central artery. I have made close examination of all this number of cases, pupils dilated with homatropia, direct and indirect method, and this reflex has always been present. The arteries are distinguished from the veins only by the larger size of the latter, and their more tortuous course, and not by any difference of color. The relation of veins or arteries in the one or the other passing over or under is not definite in the retina of the white or the black.

In my examination for a certificate of attendance given at the School of Ophthalmology and Otology, in connection with the New York Ophthalmic and Aural Hospital, I was asked to enumerate the ophthalmoscopic symptoms of morbus Brighti. In doing this I was reminded of having omitted, "the white patches," around the optic nerve, particularly between it and the macula, as being of greater importance and more pathognomonic of the disease than the stellate arrangement around the macula. I write this article with the view of asking, how is it possible to make the diagnosis of morbus Brighti in the retina of the negro, if that diagnosis must depend upon the examiner being able to see "white patches" upon a surface that is already white?

In the negro, I say, it is impossible to make the diagnosis of disease secondary to renal disease, if the existence of white patches around the disk must be taken as conclusive evidence. Of the one hundred and nine negroes, forty-two were healthy; the remainder, sixty-seven, presented themselves for eye disease with reduced vision. By examination of the urine, the history, etc., no doubt was left as to the existence of Bright's disease in nine cases. The small atrophic kidney, being the form causing, or most frequently present, when the eye is said to be the seat of Bright's disease, was undoubtedly present here. What was the ophthalmoscopic appearance? No white spots could be seen, but a most beautiful and distinct stellate arrangement around the macula, by far more typical than I had ever seen it in the retina of the white.

To summarize: The ophthalmoscopic appearance of the retina in the negro as "gauze-like," is incorrect, in my judgment; and the diagnosis of Bright's retinitis impossible, if it depends upon the existence of "white patches" around the disk, or between it and the macula.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

SERVICE OF JOHN ASHHURST, Jr., M.D.,
Prof. of Clinical Surgery.

Reported by Guy Hinsdale, M.D.

Case 1.—Lateral Lithotomy.

Our first case is one of vesical calculus, requiring the operation of lithotomy. The patient is a boy five years old, and he has shown symptoms of stone for a year or two. I will have him etherized and will sound him before you.

The symptoms of stone in the bladder are evident. There is pain, referred to the end of the penis, but due to the irritation at the neck of the bladder. This is owing to the fact that both these regions are supplied by branches of the same nerve.

Another symptom is incontinence of urine; but what I regard as a more valuable sign is a sudden cessation of the flow, followed by its return. In case of obstruction by a stone falling against the internal orifice of the urethra, a change of position will usually allow the flow to come on again. This is characteristic; the flow is suddenly checked and then the obstruction yields.

But none of these signs are absolutely pathognomonic. All the rational symptoms, except, perhaps, the sudden arrest of the flow of urine, occur independently of calculus, as in cases of tubercle of the bladder, or even as a consequence of simple inflammatory changes.

The true evidence is that gained by sounding. If the stone is small it may escape detection, from using an instrument not well adapted for its discovery; the calculus may slip around the curves of the sound and be missed; hence, we should use a sound with a short curve, which will enable it to be turned around behind the prostate if necessary. By the instrument which I now show you I once recognized a calculus which, on being removed, was found to weigh less than two grains, but which produced the most intense symptoms of urinary obstruction. In this case retention of urine constantly occurred, from the stone entering and plugging the posterior part of the urethra, and in micturition, the night before the operation, the straining was so intense that the patient ruptured a small blood vessel in each eye, producing well marked sub-conjunctival ecchymosis.

The stone may also escape detection from being covered with mucous membrane, and encysted; or it may be covered over all excepting a small portion of its surface. It is a rule, when there is reason to believe that a stone is present, though it cannot be felt with the sound, not to be satisfied with a single examination, but to examine the patient again in a few days, or in a different position, or with different quantities of fluid in the bladder.

On the other hand, one may think there is a stone present when there is not. The sound may strike the sacro iliac symphysis, and the sensation be very deceptive. The walls of the bladder itself may be ribbed and thickened, or they may have a calcareous incrustation. These are the most common sources of mistake.

For demonstration to a number of persons simultaneously, a sounding board may be attached to the instrument, but the surgeon himself, in using the sound, relies on feeling quite as much as on hearing.

In children, lithotomy is the best operation for the removal of stone, the mortality of lithotrity in children being almost as great as that of lithotomy at all ages. The mortality of lithotomy in children is about five per cent. In adults it is different; the constitution of the patient, and particularly the greater liability of the viscera to organic disease, add very much to the danger.

The size and constitution of the stone indicate, to a certain extent, the operation to be employed. If the stone is larger than an English walnut, *i. e.*, from an inch to an inch and a quarter in diameter, or if it is very hard, lithotomy would usually be the proper method to employ.

The operation which we practice to-day is left lateral lithotomy. It is the old operation of Cheselden. The median operation is particularly adapted for the removal of foreign bodies. We have, also, for large stones, the supra-pubic, the recto-vesical and the bilateral operations; but, practically, for almost all cases, the lateral operation is sufficient.

For lithotomy you need a suitable knife; that known as Prof. Gross's is a good one, and commonly answers every purpose. I have often, in children, used simply a straight bistoury. If you have to divide the right side of the prostate as well as the left, you will find it useful to have a blunt-pointed knife. The staff which I prefer is one grooved on the back; many surgeons, however, use a staff with a groove on the left side. This groove should not fade out into nothing as the end of the staff is reached, but should terminate abruptly near the end of the instrument, so that the knife may be firmly arrested without any liability to slip. The forceps, of various shapes, may, if preferred, be covered with linen or flannel, as advised by Mr. Liston, thus preventing them from slipping. A scoop is also needed.

For the operation, the first step, after the patient is etherized and tied in the proper position, is to inject into the bladder a little warm water, just enough to distend its walls, and, as it gushes through the incision, to aid in the removal of the stone by bringing it down to the neck of the organ. We then introduce as large a staff as we can get in, remembering that a child's urethra can take a staff larger, in proportion to his size, than that of an adult. Having introduced the staff, I can with it also strike the stone, which is a surety that the instrument is properly placed in the bladder.

The incision should be made starting from a point corresponding to the perineal centre, just a little to the left of the rhaphe, and from an inch to an inch and a half in front of the anus, slightly below both and a shade nearer the tuber ischii. This incision necessarily divides the transverse perineal artery; if it be made too far forward we are in danger of wounding the artery of the bulb; if, on the other hand, the knife be carried too far backward, there is danger that the rectum or the prostatic plexus of veins may be wounded; while an incision placed too far to the outer side might endanger the pudic artery.

The first incision need not divide more than the skin, superficial fascia and fat; many surgeons, however, take pleasure in exposing the staff with the first cut. The plan which I recommend I think you will find more satisfactory to yourselves and safer for your patients.

I now put the middle finger of my left hand into the rectum and feel for the tuber ischii. Having made a rather long external incision I deepen it gradually and strike the staff at as low a point as possible. With my knife now on the staff, and feeling the groove, I push it along until a gush of water shows that the bladder has been entered. In introducing my finger I gently insinuate it *above* the staff, so as to avoid any risk of getting the finger between the bladder and the rectum. With a small scoop I now readily extract the stone, which, you see, is quite a small one, though it gave the patient so much trouble. I finally inject a syringe-full of water, so that, if there is any débris, it may not be left behind.

It is not likely, in a child of this age, that it will be necessary to tie any vessels; it is probable that all bleeding will stop when the edges of the wound are brought together. The outflow of water brought the stone down, so that I felt it right underneath my finger. The difficulty of the operation in children is in reaching the bladder, and this arises partly from the fact that, at that age of life, the bladder is an abdominal, rather than a pelvic organ. In adults, on the other hand, the trouble is in getting out the stone.

The after treatment is very simple. Keep the knees together for a few days, to prevent the edges of the wound being torn apart; a draw-sheet should be placed under the patient, so that he may be constantly kept dry. For a few days the urine will escape entirely by the wound, then through both the wound and the urethra, and finally, as the healing process advances, the urine will be passed through its proper channel.

For children, the prognosis is very favorable. Unless some unforeseen complication should arise, we shall expect that our patient will certainly get well.

Case 2.—Plastic Surgery.

I next show a patient on whom, a few weeks ago, Prof. Agnew did an operation for epithelioma of the lip, and who is about to leave the

hospital. The growth was quite a large one, and a very extensive flap was brought up from the neck to close the gap left by its removal. The result is excellent, and there is very little deformity, and what there is will probably disappear in time. The upper lip will gradually come down, and the lower lip, although it is retracted, will come up, and the patient will, no doubt, be able to close his mouth entirely in a few weeks.

Plastic operations on the face are very satisfactory in their results. The face is so vascular that we can transplant large flaps and get union, whereas, in other parts of the body, not so well supplied with blood, a similar flap would be apt to slough, rendering the condition of the patient worse than before.

Case 3.—Amputation of a Finger.

This man is a carpenter. Six months ago one of his fingers received a severe bruise, and he comes here to-day with anchylosis of the joint. In his work the finger is very much in his way, and he wants it removed.

A forefinger, even if crooked, when it can be brought into contact with the thumb, is useful, and we can say the same of the little finger; but in the case of the others they are often more awkward than useful. If you have occasion to amputate these fingers above the ultimate joint, go to the metacarpal articulation. In the forefinger and little finger, on the other hand, every part that can be saved is of advantage. We often see cases in which only the thumb and forefinger or the thumb and little finger can be left, and yet the patient can make great use of such a hand. The thumb alone, with the palm of the hand, or even one joint of the thumb with one or two fingers, makes a good hand, with which a man may lead a very active life.

At the metacarpal joint the oval operation is the best, and it is made after the manner of the Larrey operation at the shoulder. A short longitudinal incision is made just below the knuckle on the back of the hand, and then curving the incisions obliquely downward through the interdigital webs, and then across the palmar surface of the finger. oval flaps are produced.

The middle finger of this hand is stiff, it is anchylosed, and no orthopædic operation would be of any use. There is not much hemorrhage attending the amputation of a finger. Slight compression made over the radial and ulnar arteries answers very well in preventing bleeding during the operation. There is not the slightest need of applying a tourniquet. There are usually two vessels to be tied. Put the arm and hand immediately at rest in a splint, and it will be very seldom that any bad consequences will follow. The operation can be done, if necessary, without ether.

JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

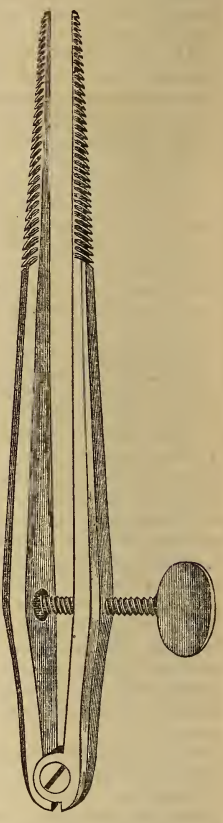
SERVICE OF R. J. LEVIS, M.D.,

Reported by H. Augustus Wilson, M.D.

A New Method of Operating for Phimosis.

At a recent surgical clinic, held in the Jefferson College Hospital, Dr. Levis showed the class his new procedure in the operation for phimosis.

The accompanying cut illustrates the instrument devised for the purpose. It is four inches long, and somewhat resembles the ordinary mathematical dividers or compasses. The legs have blunt terminations, and on their outer surfaces, for a distance of an inch and a half, are deeply serrated, with teeth set backward, to prevent the mucous membrane from slipping when traction is made. By means of the thumb screw the blades are forced apart and retained in that position throughout the operation.



The method of using the instrument is to insert it closed within the prepuce, passing it well up to the corona of the glans. By turning the thumb-screw the blades are widely separated, thus making tense the mucous membrane. Traction is then made upon the instrument, and at the same time the outer elastic skin is drawn backward, and divided near its junction with the mucous membrane, by a circular sweep of a knife. After division, the integument is retracted, exposing to view the mucous membrane beneath, which is then freely cut with scissors quite close to its attachment to the glans, leaving only sufficient to hold sutures. To this stump of mucous membrane the cut edge of skin is attached by three or four points of interrupted suture.

A cord or a few turns of a narrow roller bandage may be tightly applied as a tourniquet around the root of the penis, to render the operation bloodless. Any bleeding vessels may be ligated, but usually the hemorrhage is not sufficient to render ligation necessary.

The after treatment is the same as after the more ordinary operations.

The method so frequently adopted of removing an equal amount of mucous membrane and skin, or, as is more apt to be done, because of its elasticity, removing an excessive quantity of the normal outer skin, is open to serious disadvantages, which this procedure will avoid. The prepuce, after such operations, instead of lying normally in folds behind the corona, is, as a not uncommon result, stretched too tensely over the body of the organ, rendering erection sometimes painful, often difficult.

The writer has recently seen a case where, as a result of a faulty operation for phimosis, the penis was without integumentary covering for about one-half of its extent, and the organ, thus

deformed, was a source of great annoyance to the patient, preventing his consummating a marriage engagement.

The object of this improved procedure is to remove nearly all of the inelastic mucous membrane, in which structure the constriction generally lies, and to leave as much as possible of the elastic skin to cover and protect the glans penis. The removed and morbidly tight mucous membrane is substituted by the elastic skin, as far as necessary. The ready convertibility of the skin into mucous membrane, and *vice versa*, is recognized in operations about the nose, mouth, and other parts where the skin and mucous membrane are joined. The instrument may be obtained from the surgical instrument makers.

Periscope.

On Utero-Vaginal Injections in Childbed.

In January, before the Obstetrical Society of Dublin, Dr. W. J. Smyly read a paper on this subject. Utero-vaginal injection in childbed was a practice of great antiquity, but had of late years been practiced to an extent far exceeding that of former times. The cause of this he considered to be twofold: first, the more general adoption of the *dictum* of Semmelweis, "that puerperal fever was, without any exception, a fever of absorption, arising from the absorption of decomposed animal organic matter," which led to a belief in the identity of that fever with ichorhæmia, septicæmia, and pyæmia; and, second, the wonderful power of so-called Listerism in preventing the diseases in the field of general surgery, which leads to a desire for the employment of similar antiseptic precautions in childbed. Dr. Smyly then proceeded to show that the use of the utero vaginal douche in childbed, though apparently rational, and easy of accomplishment, was, nevertheless, one not unattended with considerable risk—either (1) from the irritation it might produce, owing to the high state of nervous excitability at the time of parturition, resulting in fits of hystero-epileptiform convulsions ending even in death, as in some cases quoted; or (2) from the displacement of uterine thrombi, causing hemorrhage; or (3) from overdistention of the uterus, giving rise to inflammation, or possibly to the escape of fluid into the abdominal cavity through the Fallopian tubes; or (4) by the entrance of air into the uterine sinuses, as suggested by the younger Legallois in 1829. Dr. McClintock had explained the mechanism by which the entrance of air into the veins in such cases took place. The veins of the gravid uterus were remarkable for their extraordinary size, their freedom of inosculation, their total freedom from valves, and their termination on the internal surface of the uterus, at the site of the placenta, by large open orifices. The same condition of the organ which caused flooding was exactly that which was indispensable for the ingress of air; so that the latter, when it did take place, was almost of necessity preceded or accompanied by hemorrhage. That he considered a most important point, and one which had been observed in almost all cases where air or other fluid had entered the circulation. The usual symptoms of such an accident having occurred were, a gurgling sound, escape of blood from the genitals, sudden sense of oppression and breathlessness, collapse, and asphyxia. The following case came under Dr. Smyly's observation, in the Rotunda Hospital, in 1879. M. M., aged thirty-five, was delivered of her first child in the hospital; the labor was natural, with the exception of laceration of the perineum, down to, but not through, the sphincter ani. All went well until the third day, when, the lochia being offensive and the perineal wound unhealthy, she was ordered to have the vagina syringed with a solution of Condy's fluid, which was done by means of a Higginson's syringe, in the ordinary way. Suddenly the woman became collapsed, respiration ceased, the pulse at the wrist became indistinguishable, and the cardiac impulse, which could faintly be felt for some time, soon ceased. The surface presented a mottled, marble-like appearance, from over-distention of the superficial veins; and in spite of all the efforts to restore vitality the woman died within twenty minutes of the accident. The *post-mortem* examination showed a quantity of frothy blood in the right heart; and when a knife was thrust into the distended iliac veins air escaped with an audible whiff. The dangers following the injection of carbolic lotion into the womb were not mainly due to the poisonous nature of carbolic acid, but, as shown by Dr. Fritsch, were really to be ascribed to the action of a heterogeneous fluid upon the nervous centres; as the transfusion of lamb's blood and the injection of salicylic acid lotion were followed by a similar series of symptoms. There was yet another danger attending the use of the vaginal douche in childbed, viz., the possibility of communicating thereby the very disease it was intended to prevent, either by direct infection from septic instruments, or by the admission of air into the womb—a circumstance which must be looked upon as somewhat analogous to making a simple fracture into a compound one. He, therefore, deprecated the use of vaginal injections, as a routine practice to be employed in every case; but admitted that in a certain number of cases, especially those in which there was already gangrene, decomposition, or the formation of gas going on in the uterus, it was most desirable. When injections were resorted to, it was most advisable that the method employed should be simple, and, at the same time, such as to reduce the risks to a minimum; for which qualities he recommended the common irrigator, with metallic tube and stop-cock, and condemned all pumping contrivances, such as Higginson's syringe, as its gum-elastic tube soon

became soft, and readily cracked—thus rendering the absorption of septic matters most probable. It was also very liable to pump in air along with the fluid, and the stream being sent in jets was more dangerous than the even flow from an irrigator.

Sunstroke and its Treatment.

Dr. D. H. Cullimore writes to the *British Medical Journal*:—

I landed in India an orthodox believer in the absolute necessity of rapidly attempting to reduce the body temperature by cold baths, and in two forms of sunstroke I am still of opinion, mainly on theoretic grounds, that the treatment is the most effectual we possess. There is, however, a third form, and one that most frequently comes under the notice of the medical officer in India—at all events while in civil employment—in which my experience has not only taught me to prefer the tepid and warm baths (from 90° to 98° Fahr.), but has led me to think that cold baths proved rather injurious than otherwise. This third form was probably the disease, complicated with malarial fever, from which the Marquis of Ripon has lately recovered. The varieties of sunstroke to which, in my opinion, the cold bath should be restricted are these:—

The first is the sudden stroke from the direct effect of intense sun heat, combined with great fatigue, and predisposed to, perhaps, by the use of stimulants. This form is rapidly fatal; it most frequently occurs in young, vigorous, unacclimatized men, whose internal organs are probably sound; and is attended with loss of consciousness, pungent heat of skin, perhaps convulsions, and death from syncope, owing either to stunning of the brain, or to paralysis of the conducting nerves and their centres, brought about by a coagulation of the albuminous bodies in the nerves, muscles, etc. Here the immediate and repeated use of the cold bath, with the application of cold to the head, seems rational enough. I have seen but one case of this kind; and death was of too rapid occurrence to allow any treatment to be adopted with any chance of success. There were *post-mortem* signs of cerebral congestion and effusion of blood. The lungs were considerably engorged. The patient had an epileptic history.

The second form, in which the immersion of the body in cold water will reduce the temperature so as to permit the renewal of the suspended functional activity of vital organs, is that kind of heat asphyxia known to occur on board ship in narrow tropical seas, or ashore in the crowded barrack-room.

The third variety, and that in which my experience has led me to discard the cold and adopt the tepid and warm bath, may be described as follows: It occurs most frequently among acclimatized district civilians—engineers, police and medical officers—men whose duties necessarily expose them, at times, to great and prolonged heat, considerable fatigue, and a good deal of discomfort, while sojourning in tents or travelers' bungalows. They are probably tainted with malaria, and may have occasionally suffered from attacks of congestion of the liver and dysentery. While on a tour of this kind, the patient elect begins to feel irritable, tired, and out of sorts; he tries to look bright and pull himself together. After a day or two, the heat of skin increases, and he ceases to perspire; there are headache and intolerance of light; and when considerably done up he returns home, and after a sleepless night sends for the Doctor. His face is now flushed; there is intolerance of light and sound; perhaps delirium and muscular twitches; the skin is dry and burning; the temperature 106° or 107° Fahr., with exacerbations if complicated with fever. The pupils are often contracted; and there may be tenderness over the hepatic region, with a yellow conjunctiva. Patients suffering as described generally recover if treated promptly. The disease is liable to recur, and a sojourn in Europe is advisable, but not absolutely necessary.

The treatment which I have adopted in several cases of this affection, and to which, were I a patient myself, I should wish to be subjected, is as follows: A warm bath, to be repeated according to the judgment of the medical attendant; cold to the head, in the form of irrigation, if the patient will bear it; and removal to a cool, dark room, with a punkah. A thermantidote would be a great advantage; it is, however, necessarily restricted to public institutions, and I have never seen one in use in India. Aconite and belladonna, in from three to six minim doses, should be given every two hours. This combination is invariably followed by free perspiration, but a coincident reduction of the temperature does not always accompany it. Still it is the best means of attaining that end, at the same time controlling the meningeal disease. Bromide of potassium is a useful addition in some cases: chloride of ammonium in others; and quinia, if there be a malarial complication. Quinia, unless in cases of ague, does not, I think, reduce the temperature of the body. Potash water is the best beverage.

The Treatment of Anthrax.

We read, in the *Paris Médical*, that this subject was under discussion in the "Société de Chirurgié," on March 30th.

M. Le Fort, following the example of the German and Russian surgeons, has used a sharp curette in three cases of anthrax. He made a crucial incision on the anthrax, and removed the greater part of it by means of a sharp curette. He was obliged to desist, owing to the patient's being in extreme pain; however, a rapid cure followed. In a third case he made use of chloroform, and the patient was able to leave the hospital after seven days. M. Sée has also used the curette on anthrax after making a crucial incision, and he obtained an advantage both in the duration of treatment and the intensity of the general phenomena. He has, however, given up this method, and adopted Hueter's process, which should be used when the disease first appears. A small incision is made on the periphery, through which a curved tenotomy knife is introduced, and all the accessible fibrous parts are dissected. This should also be done on a few other points. All the little cells con-

taining pus are thus united into one, and an ordinary abscess is thereby formed. The teguments suffer but very little loss of substance, and healing very rapidly follows. M. Tillaux observes that this method was suggested many years ago by M. Alph. Guérin. He does not approve of such incisions in all cases, but would reserve them for when the anthrax is very painful. M. Marjolin believes that success depends upon the incisions; they should be numerous, and extend beyond the limits of the affected parts.

M. Le Dentu has, within some time past, attended four very serious cases of anthrax, which he boldly incised, and they healed. In all these cases a marked amelioration rapidly followed. He believes an anthrax should not be incised before the sixth or seventh day. With one of his patients he used, as a dressing, a three per cent. solution of boracic acid mixed with half its bulk of tincture of iodine.

In the proceedings of the Société de Chirurgie for April 6th, reported in the *Paris Médical*, we find that M. Sée again brought up the treatment of anthrax, and having read M. A. Guérin's article on this subject, he insisted on the difference existing between that and Hueter's treatment. Hueter removes all constrictions of the cellular tissue in every direction, while Guérin simply made subcutaneous incisions. By the aid of small openings M. Sée dissects all the freni which extend from the skin to the superficial aponeurosis, and he also uses those openings for antiseptic injections.

M. Labbé called attention to a diversity of opinion existing among surgeons. Some (Broca) recommend total extirpation of anthrax, while others favor a palliative treatment. These opinions are based upon particular facts.

There are cases in which anthrax heal readily, and almost of their own accord, while in others elimination is difficult. Indurated anthrax, also called ligneous, requires large and numerous incisions, and sometimes, too, ablation, as recommended by Broca. M. Després treats anthrax without incisions, and out of forty-nine individuals he only lost three; two who were diabetic, and one who, when he came under his care, was already suffering from phlebitis. An anthrax formed out of a reunion of furuncles requires no incisions; a gangrenous anthrax cannot hasten the elimination of the eschar.

M. Trélat desires the fact known that Broca, who proposed ablation for anthrax never performed that operation. Therapeutics should vary according to the cause of anthrax. M. Trélat concludes by offering the following specified treatment: a limitation of the tumor, the elimination of the secreted matters, and antiseptia.

M. Tillaux can see no difference between Hueter's process and that of Guérin. Incisions may not be useful at the start, but when anthrax has reached a certain stage, they reduce fever and bring relief.

M. Verneuil is less affirmative. He thinks that out of one hundred cases of anthrax there are eighty which should be left undisturbed. The two chief indications are these: an anthrax should be incised when it is very painful, and when it is not self-limiting. As regards diabetic patients, their case is peculiar. M. Verneuil discourages all incisions with the bistoury, because of their liability to hemorrhages. The thermo-cautery should be used, and with it incisions made all around and extending beyond the limits of the anthrax. Subcutaneous incisions are considered by M. Verneuil as operative subtilties.

M. Th. Anger, has followed with success Nélaton's precept, of making large crucial incisions, and extending them in depth, so that the four flaps should be movable upon the deep parts.

M. Boinet states that on diabetic patients he makes seven or eight star-like incisions; in these he inserts arrows of Cangnoin paste, and then dresses the parts with tampons of lint saturated with tincture of iodine.

Rules for Introducing the Uterine Sound.

Cameron gives these judicious directions in the Glasgow *Medical Journal*:—

It may seem unnecessary that we should here repeat the warning, never to pass the sound where there is any reason to suspect pregnancy, as then you incur the serious responsibility of producing abortion; but the too frequent mistake of overlooking such a condition demands the repetition of this caution. The utmost care should be taken in the introduction of this instrument, because without this you may perforate the tissue, perhaps already softened, or set up peritonitis. Malignant disease of the cervix or fundus excludes its use, as also acute inflammation of the uterus or its appendages. It has been recommended in special cases; but it is better to avoid any examination during menstruation, and in no case should the sound be passed without previously having made a careful bimanual examination.

To introduce the uterine sound, place the patient as in passing the speculum, and pass two fingers of the right hand, viz., the index and middle, up to the cervix, with the knuckles toward the pubes, and in the groove formed by the fingers glide the instrument along, keeping the concave surface directed backward. Never forget to have the sound warmed previous to its introduction. If the passage is straight, as in females who have never had children, the index finger will be sufficient to guide the sound. If the os is directed downward and forward, the instrument is passed into the cavity without rotating the handle; if the os is, however, directed downward and backward, the instrument is only allowed to enter the external os, and then the handle is turned so that the point of the sound may be directed upward and forward.

If there be any difficulty in making the instrument enter, this is often overcome by slipping the point of the instrument from the finger tip into the os.

We noticed previously that the instrument usually passes into the uterine cavity for two and a half inches, as indicated by the nodule upon the convex edge of the sound. To measure the distance it has passed, place the finger point

firmly upon the portion at the os, and keeping it there, withdraw the instrument, when you can at a glance observe by the engraved figures how far the sound has passed. With sufficient care, we can usually succeed in passing the sound into the healthy womb; but the most experienced finds it often exceedingly difficult to introduce it in certain affections of this organ.

In the various flexions and versions, as also neoplasms projecting into the cavity, we find much to oppose our attempts to pass the sound. In some cases you will even fail, and it is only by the greatest patience that success may reward your efforts. Generally its introduction is free from bleeding, and if traces of blood are seen, it is usually the result of congestion, cancer, fibroids, or polypi. Force should never be used, as you will simply expose your patient to much danger. To lay down special rules were vain, for experience must guide you in each case. Every instrument should have a mark upon the flat surface of the handle, so that the operator may have no difficulty in seeing at once how the instrument is situated. In replacing the displaced organ, say in displacement backward, the movement is effected by a rotation of the handle through half a circle, so that the portion acting within the uterus may rotate in the smallest degree. A simple twisting of the handle is apt to give pain, and may cause injury. In conclusion, the uterine sound, as before stated, should never be used without previously making a careful examination. So much is this overlooked that a very eminent obstetrician proposes to have a uterine sound made, having for its handle a small representation of a fœtus, which may be the means of causing the operator to pause before using the instrument.

The Use of Lime in Gout and Allied Diseases.

Dr. H. C. March writes, in the London *Med. Times and Gazette*, March 19th, 1881:—

In the treatment of gout we are apt to reach a troublesome stage. The subject, let us say, is fat and plethoric. He has an active mind, but a slothful body; a big belly and a disposition to keep it full. He gladdens his heart with corn and wine. All at once occurs a furious attack of podagra. The doctor is promptly summoned, who restricts the too ample diet, applies favorite lotions, and fires into him a fusillade of purgatives, alkalies, and colchicum, with a reasonable amount of benefit. For now he can limp a little, the nocturnal exacerbations are over, and the inflammation is gone. Indeed, the treatment may have been so successful that the circulation has become feeble, the skin chilly, and the appetite poor. But the foot remains swollen, and marked with purple veins, and when it is placed on the ground, "the blood rushes into it," as the patient says, and it assumes a livid appearance. This state of things may last for weeks, in spite of tonics and general treatment; but we all know that it is rapidly cured at Buxton or at Bath.

The notion of administering lime had often occurred to me. The difficulty was to find a satisfactory formula. Lime-water has obvious disadvantages. Many of the salts of lime are insoluble. The acetate, which is both soluble and stable, is excessively disagreeable. At last I thought I would manufacture a citrate, and set about it on this wise. I neutralized a quantity of liq. calcis saccharatus with citric acid. The compound was perfectly clear, and remained so all day; but the next morning, much to my astonishment, I found a copious, dense, white precipitate, which every chemist will readily understand was due to the slow conversion of the citrate of lime into the oxalate. The experiment was repeated, always with the same result; but presently I discovered a rather curious fact, and one that I cannot very well explain—that if the saccharated solution of lime be treated with a considerable excess of citric acid, this conversion into the oxalate does not take place. This is certain, because I have ascertained that citric acid does not dissolve oxalate of lime. Another curious fact should be mentioned, that if this acidulated citrate of lime be now neutralized with carbonates of the alkalies, chalk is not formed, the solution remains perfectly clear. Thus, then, the difficulty was removed, and the following is the formula I now employ:—

℞.	Liq. calcis sacch.,		℥ iv	
	Acid. citric.,		℥ iv	
	Tr. aurant.,		℥ ij	
	Aquæ,	ad	℥ iij.	M.
℞.	Sod. bicarb.,		℥ j	
	Pot. bicarb.,		℥ j	
	Am. carb.,		℥ ss	
	Aquæ,		℥ vj.	M.

Sig.—A tablespoonful of the acid mixture, with two of the other, to be taken in effervescence.

Of course, to this may be added Rochelle salts, or colchicum, or quinine, or anything, in fact, that the fervid practitioner may desire. But as the prescription stands, I have obtained from it the best and speediest results in those cases of chronic after-gout that I have endeavored to describe. The swelling of the foot subsides, the turgid veins contract, the strength of the joint increases, the appetite returns.

What is to be said of this therapeusis? A hundred and fifty years ago gravel and chronic gout were treated by lime-water with great success. Christison maintained that urate of lime is more soluble than uric acid. Clinically speaking, in the cases I have indicated, citrate of lime would seem to have an action specially tonic: an action that also appears to be of much benefit in some low sweating forms of rheumatic fever.

High-heeled Boots and Backache.

The following observations are made by Dr. C. D. F. Drury, in the *British Medical Journal*, March 26th:—

I am certain that, in women, the most frequent cause of backache is leucorrhœa; and until this (whatever may be its cause) is cured, the backache will continue. My experience is that considerably more than half the married women, and very many unmarried ones, suffer, off and on, from leucorrhœa. I believe the most prolific cause of "whites," in unmarried women, to be

long standing on the legs and bodily fatigue. Another cause of backache is the wearing of high-heeled boots, which necessitates the continuous action of the muscles of the lower part of the spine, in order to maintain the proper balance and erect position. I have had four such cases, and I know of another, all cured by discontinuing the use of high-heeled boots. It is really surprising what very serious symptoms may arise from such an apparently trivial cause. The following is the first case about which I was consulted:—

M. A , aged 17, an assistant in a large drapery house, a delicate-looking blonde, of pale, lymphatic temperament, subject at times to hysteria; had been quite regular since she was fifteen ; and occasionally the catamenia were very profuse. She complained of almost nothing except severe backache, "a feeling as if her back had been bruised," which frequently prevented her from sleeping at night. She had had "whites" on several occasions, even sufficient flow to make her think she was menstruating; but at present she had none, and felt better and stronger than for some time. with the sole exception of backache. Her appetite, though generally capricious, was now good. I prescribed rest, change of air, valerianate of iron, and a large belladonna plaster to the back, and directed her to lie at least an hour, morning and afternoon, on the sofa, with a cushion well pressed into the back, and to take a short walk twice a day. She obtained a fortnight's holiday. When she returned the backache was no better; in fact, worse; so much so, that her mother was determined I should see it; she was sure "there must be something wrong with my daughter's back." She now, also, complained of aching in the calves of the legs, and great tenderness in both groins. Her mother said she had noticed that her daughter had always complained more on Sunday nights, and all day on Mondays; but, during the last week, every day was the same. Her daughter did not dislike her employment, and, indeed, was now most anxious to return. I examined the back carefully; nothing seemed wrong there; nothing was to be seen on the calves; there was no glandular enlargement, nor any swelling in the groins, though there was tenderness to touch. Her urine was normal. I was about to leave the room, when I noticed that she was wearing very high-heeled boots. On my return to my room, I told the mother that her daughter must have another fortnight's holiday; must carry out my directions as to medicine, rest, etc., as before; and in addition, must wear woolen stockings, a pair of soft-soled house-slippers always; and when she went out, put a pair of goloshes over them, but at no time wear boots. In a fortnight she called to tell me she was quite well, and intended to return to her employment on the Monday following. I then explained to her that the sole cause of her backache was the wearing of high-heeled boots.

"Inward Fits" in Children.

Dr. Charles Bell writes on this subject, in the Edinburgh *Medical Journal*, December, 1880:—

This is a common disease in infants within a few months after their birth. The child lies as if asleep, but the eyelids are partially open and have a twinkling motion, the eyes are turned up so as to show the white, the muscles of the face and lips have a tremulous movement, producing the effect as if the child were smiling—a circumstance which has given rise to the beautiful idea that angels are whispering to it, which has been finely illustrated by Moore in his Irish Melodies, under the name of "The Angel's Whisper." As the disease increases the breathing is occasionally interrupted, the features become pinched, and a livid circle forms around the mouth and eyes. There is restlessness and starting during sleep, and the child is disturbed by the slightest noise, and sighs and brings up wind, after which it relapses into a drowsy state. In simple and mild cases the attacks generally disappear as the child's strength improves; but if it is improperly treated, the drowsy state increases, and a sort of thrush appears, accompanied by feverishness, sour vomiting, watery stools, gripes, which may terminate in regular convulsions.

Dr. Armstrong has divided this disease into four stages, viz.: 1st, inward fits; 2d, fever and thrush; 3d, sour vomiting; 4th, convulsions. Underwood did not consider it worthy of being called a disease, and that he knew no complaint which ought to be called "*inward fits*;" the symptoms described above were worthy of attention only from the risk that they might pass insidiously into regular convulsions—an amply sufficient reason for their being carefully attended to and means taken for their being removed.

The incipient stage which occasioned the name may occur at very early periods, and the earlier it does so, there is the greater danger to be apprehended. Nurses often use the terms on insufficient grounds, and in consequence the mother is apt to become needlessly alarmed, and to have recourse to very improper medicines, such as Dalby's carminative, Godfrey's drops, Soot drops, etc., which are liable to produce serious results.

It has been connected with spasm of glottis, with acute asthma, the peculiar species of convulsions, cerebral croup, laryngitis stridulus, thymus, asthma, or spasmodic croup, by different authors.

Treatment.—It is clear that the symptoms which have just been described are the result of something irritating the bowels, and that a dose of magnesia will in general be sufficient to remove it. Should this not be the case, it may be necessary to attend to the state of health of the nurse, and to give the child the benefit of change of air.

Detection of Fuchsine and Certain other Aniline Colors in Wine.

We learn from the London *Chemist and Druggist* that, in the *Berichte der Deutschen Chem. Gesellschaft*, January 10th, 1881, F. König describes a very simple method for testing wine, or any other liquid, for fuchsine, by means of which mere traces of the color may be detected. The method is based upon the affinity of fuchsine for wool, the ready decomposition of the latter by caustic potash, and the solubility of rosaniline in ether.

The author manipulates with wine in the following way:—

About 50 cc. of the wine to be tested are treated with excess of ammonia until the red color passes into a dirty green. About half a gram of clean white wool is then immersed in the liquid, and the whole boiled until the entire quantity of alcohol and ammonia has evaporated, the green color gradually passing into a brownish red. This treatment suffices to destroy the color of wine, while fuchsine or other aniline colors become fixed upon the wool. The wool is then taken out of the liquid, washed with water, and wrung. In the case of samples of wine containing a considerable quantity of fuchsine, the wool becomes at once strongly colored; but, as even a strongly-colored, unadulterated red wine imparts to the wool a reddish tinge, to avoid error the piece of wool must be put into a test tube, and moistened therein with a solution of pure caustic potash containing about one-eighth to one-tenth of the dry alkali. The test-tube is then carefully heated, and continually shaken, until the wool has dissolved to a brown liquid. Upon cooling, the solution is first treated with about half its volume of pure alcohol, upon which an equal volume of ether is then poured, so as to form a layer above the alcohol. The whole is then shaken up, at first gently, and then more vigorously, and after a few seconds a layer of ether, which contains some alcohol and all the rosaniline present in the wine, forms above the brown liquid. This is either poured off or, preferably, removed by a separatory funnel, and treated in a test-tube with a drop of acetic acid, whereupon, if the wine operated on contained even a mere trace of fuchsine, a red tinge is produced. The delicacy of the method is chiefly due to the concentration of the fuchsine of 50 cc. of wine in a few cc. of potash solution, from which it is easily transferred to the alcoholic ether. The true coloring matter of wine is destroyed by the above process.

In the case of red wine containing 1 mg. fuchsine per litre the other assumes an intense red color, and even a wine containing only 0.04 mg. per litre (a dilution of fuchsine which is scarcely visible in a considerable layer of the water containing the color in this proportion) imparts to the ether a most decided red tinge, which cannot be mistaken, the coloring matter of even the darkest red wine not passing over into the ether solution. To detect such a dilute fuchsine solution the only way hitherto available was by evaporating a considerable quantity of the wine to be tested, and examining the residue.

Certain other aniline colors, such as violet and blue, admit of detection in the same way.

By working according to the author's method with known volumes, prepared by dissolving fuchsine in red wine, a scale may be prepared by means of which approximate quantitative results may be obtained.

Sanitary Rules for Public Buildings.

The following rules, says the *Sanitarian*, to be observed in the construction of all buildings erected under her Majesty's Office of Works, have been prepared and issued by the Secretary to the Office of Works:—

1. All water-closets and urinals shall be constructed so that one wall, at least, of such closets and urinals shall be an outer wall of the building.

2. All soil pipes shall be carried outside the building, and ventilated by means of pipes leading the foul gases above the highest point of the building. Such pipes to be carried to points removed from chimney stacks.

3. Separate cisterns shall be constructed for the water-closets and for the general purposes of the building. No tap or "draw-off" shall be affixed to any pipe communicating with a cistern supplying a water closet or urinal.

4. All waste pipes and overflow pipes of cisterns shall terminate in the open air, and be cut off from all direct communication with drains.

5. Great attention shall be paid to insuring thorough ventilation in all rooms. Rooms so high that their ceilings shall be more than two feet above the top of the windows, corridors, staircases and other open spaces, shall be specially ventilated, so as to prevent the accumulation of stagnant air.

6. All main drains should, where practicable, be formed outside the building. In the event of its being necessary to carry a main drain underneath a building, it must be trapped immediately outside the main wall, and a ventilating pipe must be carried from that point to the highest part of the roof, as under Rule 2.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The advantage of the treatment of certain gynæcological cases by absolute rest, is set forth by an illustrative case by Dr. H. R. Bigelow, of Washington, in a reprint from the Maryland *Medical Journal*.

——We have received the Announcement of the Medical Department of the University of Pennsylvania, for the one hundred and sixteenth Annual Session, 1881–82, from which we give the following calendar:—

1881.

Sept. 12. Preliminary Course opens.
" 28. Competitive Examination for Scholarships held.
" 29. Examination for Admission to Advanced Standing, and Re-examination of Undergraduates.
" 30. Examination for Admission.
Oct. 3. Winter Session opens.

1882.

Feb. 27. Examination of Graduating Class begins.
March 1. Examination of First and Second Year Students begins.
" 15. Annual Commencement.
" 16. Examination for Resident Physicians, University Hospital.
" 20. Spring Session opens.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

STATISTICS OF SICKNESS IN BENEVOLENT SOCIETIES.

There is a valuable source of statistics relating to the amount of sickness in certain classes in this country, which, so far as we know, has not been utilized by our sanitary students. We refer to the reports of those benevolent societies which pay their members a certain sum when they are incapacitated by illness from pursuing their avocations. The most important of these societies is the Independent Order of Odd Fellows. For the experience of this influential organization we are indebted to the courtesy of MR. JAMES B. NICHOLSON, Grand Secretary of the Grand Lodge of Pennsylvania.

The attention of this Order is naturally turned to a study of the prevailing average of sickness, because the question of this average for each year of an individual's age is of importance in estimating the obligations which a Lodge assumes on receiving a member, and in devising a system of dues which shall bear equitably on every person. And all the statistics which have been accumulated for years go to prove that there is a steady rate of increase in sickness for the average individual, proportionate to his advance in age. Years ago this fact was established by the authorities of Great Britain in their investigations into the condition of friendly societies. The only reasonable question that remained was, whether the conditions of health and disease on the continent of North America were the same as in Great Britain. That question may also be considered as answered—all statistics showing that the yearly increase takes place in the new world as in the old; that the rate is slightly lower among our members than among members of benevolent societies in Britain; and that in all these organizations the rate is much lower than with the general community.

In Pennsylvania there is, throughout all the lodges, there has been, as might be expected, a steady increase in the average of sickness as the Order grew older, and a larger number of its members approached old age. This is strikingly illustrated in the following table, which gives the

general average of sickness, in weeks, per one hundred members:

In 1873,	this	was	62.25.
In 1874,	"	"	62.91.
In 1875,	"	"	67.22.
In 1876,	"	"	64.47.
In 1877,	"	"	77.39.
In 1878,	"	"	80.90.
In 1879,	"	"	89.78.

Classifying the lodges by hundreds, the statistics render apparent how much less time is lost by sickness in the junior lodges than in the old ones. Thus, the oldest 100 lodges in this State lost, in 1879, 125.81 weeks' sickness for each 100 members; while the 100 junior lodges lost but 22.35 weeks' sickness for each 100 members. A mathematical law has been deduced from the study of this progression, to this effect. It appears that after making due allowance for the causes that produce fluctuations, the existence of a law that regulates the demand for sick benefits is as clear as any mathematical demonstration can be made.

In the lodges numbering from 1 to 100, the increase in five years was twenty-four weeks for each one hundred members. In the lodges numbering from 501 to 601, the increase during the same period of time was thirteen weeks, while in the lodges numbering from 701 to 801, the increase was five weeks. Thus showing that the ratio of increase in five years was greatest in the oldest lodges, and least in the younger lodges. Nothing can be clearer than the fact thus demonstrated by the experience of the Order, that in every lodge there will be an increased demand for benefits in the future, as the lodges grow older, and that the ratio of increase will change and be enlarged with each decade of years, until the maximum demand is reached, on account of the maximum of sickness having been attained. The financial bearing of these facts on the prosperity of the Order is perfectly well recognized by the able men who have its interests in charge.

The reports of Mr. J. W. Hallam, Grand Secretary for the State of Delaware, present the statistics of the Order in other forms, one of his tables showing the number of members sick at each age, with the number of weeks' sickness, and the number who died. While another table shows, by decades, the number, averages and percentages of members sick at each age, the number of weeks' sickness, and the number who died. A part of this table we make room for, as it strongly shows the increasing invalidism with advancing life:—

AGE.	Total Membership.	No. of Members Sick.	No. of Weeks' Sickness.	Average No. of Weeks each Member is Sick.
From 21 to 30.....	858	248	1001	4.
" 31 " 40.....	830	361	1946	5.
" 41 " 50.....	423	332	2279	6.83
" 51 " 60.....	191	220	1488	6.76
" 61 " 70.....	63	127	1230	9.85
" 71 " 86.....	22	43	647	15.

It is believed, also, that temporary causes, especially business prostration, increase the amount of sickness, even among active, fairly well-to-do males, as most of the members of the I. O. of O. F. are. Thus, the Grand Secretary remarks of the sick rate in 1879, which mounted up to the heavy figure of 89.87 weeks for each 100 members:—

The amount of sickness for which benefits have been paid, if distributed *pro rata* among the entire membership in the jurisdiction, would assign to each member during the past year a sickness of six days, six hours, fifty-eight minutes and forty seconds duration, an increase of nearly two days within the past five years. It was thought that the steady increase in the average amount of sickness was abnormal, arising largely from business depressions and want of steady employment. It is yet too early to declare that there is no ground for the idea. The experience of the current year will be looked for with some anxiety, to ascertain whether the increase will continue upon the same ratio as it has done in the past, or whether the revival of business will not have a favorable effect upon the ratio of sickness.

It is highly probable that this is an exciting cause of many maladies. The depressing effect of anxiety, grief and fear, of disappointment and discouragement, are too well known to need special mention.

These observations by no means exhaust the documents of the Order in their hygienic and sanitary interest, and we refer to them rather to bring them to the attention of special students in that branch than for any other purpose.

Notes and Comments.

Iodoform as a Vermifuge.

Prof. F. L. Sim, M.D., of Memphis, relates, in the *Mississippi Valley Medical Monthly*, for May, the case of a young man who presented a number of distressing symptoms, such as intolerance of light and sound, with great debility and nervous prostration, impaired digestion, disturbed sleep, etc. He was first seen in April, 1876.

A visit to Hot Springs, Ark., during 1878, greatly improved his health, but upon returning he soon relapsed into his former condition.

May 1st, 1880, during the Doctor's absence, he called upon another physician, on account of disease of the prostate, for which he was advised to take one grain of iodoform three times a day. After continuing this treatment for some time, he observed some segments of tapeworm in his stools. He was now advised to take santonine in fifteen grain doses, but this vomited him so severely that its use was abandoned. A half drachm of oil of male fern was then ordered, to be followed in four hours by a large dose of castor oil and turpentine. This caused the expulsion of eighteen feet of the worm.

During the succeeding two or three weeks the patient greatly improved. At the end of this time he again had recourse to the iodoform for relief of uneasiness about the neck of the bladder. Three days later segments of the worm were noticed; this continued as long as the pills were taken regularly; when they were discontinued the proglottides ceased to pass.

October, 1880, he was ordered the male fern as before, this time resulting in the expulsion of thirty feet. Although no head was discovered, we hoped the entire worm had been passed.

The health of the patient continued to improve for about one month, when the former symptoms again made their appearance. The iodoform was this time resorted to for diagnostic purposes, and after a few days' use of it segments of the worm were found in the stools. Its use was persisted in for several days before adopting curative treatment, with the view of sickening the worm, thereby rendering its complete expulsion more certain.

Early in January, 1881, a large dose of kousso was taken, but at once rejected by the stomach. A drachm of oil of male fern (double the former dose) was then taken, followed by a brisk cathartic four hours later. This resulted in the expulsion of twenty one feet, and probably all, of the tapeworm, as the iodoform has been taken several times since without discovering it. The health of the patient is entirely restored; he complains of nothing, eats heartily and his digestion is perfectly good.

Another case is related; that of a gentleman who complained of intolerable tickling and itching about the rectum and anus, becoming greatly aggravated after going to bed at night. This distressing feeling had annoyed him for months; recently, however, it had grown so violent that he was compelled to seek relief. He was ordered a suppository of cocoa butter, containing seven grains of iodoform, to be introduced into the rectum at bedtime. The following morning he reported having passed "a handful of needle-worms" (oxyuris vermicularis). Complete relief was obtained in about one hour after the introduction of the suppository, and the first good night's rest enjoyed for many nights followed. One grain of iodoform was then given by the mouth three times a day, the suppositories to be repeated if itching returned. No suppositories were subsequently indicated. After a continuation of the iodoform four days the worms began to pass, and were found in every stool for six days. No evidence of their presence has since existed.

In two other instances during the administration of the iodoform to adults for other purposes a number of the ascarides lumbricoid were ejected.

Where tapeworm is suspected the Doctor thinks the iodoform will prove of great diagnostic value. He does not regard it as a vermiciticide, as the segments were expelled alive. How it acts, he will not undertake to state, but thinks it quite probable that the odor proves intolerable and actually "stinks him out."

Menstruation after Ovariotomy and Gastrectomy.

M. Ormières, in an interesting thesis (Thèse de Paris, 1881) cites upwards of 150 cases and observations collected from all sources; in many cases after complete extirpation of the ovaries menstruation took place, just as before the operation; and even after the ablation of the body of the uterus (gastrectomy) and the two ovaries, menstruation has, in a certain number of cases, persisted.

The author, from the consideration of these cases, arrives at the following conclusions as regards the menstrual flow and its relations with the ovaries: The congestion which determines the menstrual flux is the consequence of a vasomotor reflex of which the point of departure is the ovary. This organ, at the period of puberty, enters on its period of functional activity and becomes the seat of a continuous cell formation, which reacts on the central nervous system, and

thus determines, at the moment when excitation is most marked in the ovary (when the rupture of the Graafian follicle is imminent), that state of congestion which determines the monthly flow. But how explain the occurrence of menstruation after extirpation of the ovaries. If there is absence of ovaries or atrophy of these organs in the young girl menstruation never takes place. It would seem that when once the perfectly developed ovaries have reacted on the nervous system; induced menstruation and "habituated the uterus to regenerate monthly its mucous lining membrane, the phenomena of nutrition and cellular reproduction will from that time forward continue spontaneously." The author then considers that the reflex of menstruation, as also the menstrual discharge, may have its source in any part of the genital apparatus, from the ovary to the vagina. From the numerous considerations embodied in the thesis the following general law may be formulated: "Menstruation has in all cases, its origin and the cause of its periodicity in the functional activity of the ovarian epithelium, and later, or perhaps from the beginning, in that of the epithelium of the mucous membrane of the vagina and uterus."

Complete Obliteration of the Common Bile Duct, Without Jaundice

At a recent meeting of the Société de Biologie, April 23d, MM. Hanot and Gombault reported a case of sclerosis of the pylorus, with fibrous transformation of the hilum of the liver. On dissection and examination with the microscope, it was found that the common bile duct, the cystic duct and the hepatic artery were completely obliterated; the obliteration of the portal vein was not complete. There had never been any trace of jaundice while the patient was alive.

MM. Hanot and Gombault consider that the pathogenesis of jaundice is far from complete elucidation, and that the facts in this case might be variously interpreted. In the pathogenesis of jaundice, the condition of the excretory bile ducts is not the sole subject for consideration; the state of the vessels which carry to the hepatic parenchyma the elements of the secretion, as also the state of the secreting organ itself, are both subjects of primary importance.

In this case the ductus communis choledochus was obliterated; but, at the same time, there was complete obliteration of the hepatic artery, and incomplete closing up of the portal vein. It may then be admitted that the biliary secretion was, if not abolished, at least very notably diminished, so that its retention did not suffice to produce the phenomena of icterus.

The tissue of the liver presented the microscopic lesions, which are produced experimentally by ligature of the common bile duct and portal vein, a sort of compound cirrhosis, venous and biliary at the same time.

On Nerve Stretching.

The effects of nerve stretching, as reported in our foreign contemporaries, seem to be by no means uniform. Sometimes the most obstinate neuralgias are at once and permanently relieved, at other times no appreciable improvement is effected. Here is a favorable example from the practice of Dr. W. J. Naismith, reported in the *Lancet*, May 14:—

J. L., a miner, aged fifty four, was admitted with intense sciatica on the left side. He had formerly been a laborer, when he was exposed to all weathers, and he was much addicted to alcohol drinking. His appearance was strikingly indicative of a broken-down constitution. He had been in various hospitals within the last seven years, during which period he had been a martyr to his complaint. He had had all kinds of treatment, including blisters, liniments, subcutaneous injections, courses of iron, arsenic, quinine, etc., together with acupuncture, and the application of the button cautery, but all to no purpose. It was therefore resolved to try stretching the sciatic nerve; and the operation was performed under chloroform, in the usual manner, and without strict antiseptics, though dressings of carbolic oil, one to twenty, were used. For the first week there was a slight rise of temperature, and pain was complained of in the wound, but these symptoms subsided, and the man made a good recovery, expressing himself grateful for his entire immunity from his old sciatic pain since the day of the operation. This patient was under observation for three months, and during that time there had been no return of his complaint.

Race Differences.

The study of race differences, as exhibited in the bony skeleton, includes not merely the skull, the facial bones, the tibia, the os calcis, etc., but also the form of the scapula. This is studied in the last volume of the *Journal of Anatomy and Physiology* (1880), to which Professor Flower and Dr. Garson contribute an important article upon the "Scapular Index as a Race Character in Man." This index is the numerical expression of a proportion between the length and breadth of the scapula. The "infra-spinous in-

dex," *i. e.*, the distance between the root of the spine and the inferior angle, is also taken into account. Broca was the leader in this direction. In fourteen races (200 Europeans, 14 Australians, and 21 Andamanese,) the authors found the Europeans to have a scapular index of 65.2 and infra-spinous index of 89.4; the Australian indices, on the other hand, were 68.1 and 93.3, and the Andamanese 69.8 and 92.7.

The difference in the volume of skulls of the different races has been afresh investigated by Le Bon. In 100 skulls of Parisians of this century, 11 were over 1700 cubic centimeters in capacity; of 100 negro skulls not one reached this size. Among skulls of native Australians and of the Pariahs of India, he did not find one over 1500 cubic centimeters capacity; the largest skull found in these races was 400 cubic centimeters less than the largest in the modern French race.

Infiltration in Mammary Cancer.

In the last volume of the *Journal of Anatomy and Physiology*, Dr. Creighton calls attention to the hard cancers of the breast, and to their infiltrating properties. He starts with Sir J. Paget's definition of infiltration, as being the insertion of structures proper to cancer in the interstices of the proper tissue of the part, and then discusses two propositions: 1. That the initial condition of the original epithelium is, in many cases, that of an actual or literal infiltration into the surrounding stroma; and 2. That it is this literal and actual insertion of epithelium that determines, through the mimicry of infection, the familiar appearance of alveolar or linear groups of epithelial cells springing from the stroma cells at a number of independent centres. In another admirable paper on the pathology of sarcoma, he takes occasion to say, with regard to the origin of such tumors, that there is not a survival of the embryonic tissue itself, but of the *tendency to form* embryonic tissue.

Dr. Warren's Surgical Inventions.

The *Virginia Medical Monthly*, for June, contains an article from Dr. Joseph H. Warren, of Boston, defending his new surgical instruments against the adverse strictures of some critics at the meeting of the American Medical Association. It is evident from his account that certainly some of these criticisms were made altogether too hastily, and with an extremely superficial knowledge of the subject. Dr. Warren says:—

It has also been said that my instruments are complicated and liable to convey disease in their joints. In answer to this, we need only say that any one, upon examination, can easily see that the instruments are of the most simple arrangement, combining the wedge and screw in shape, and moreover, can be very readily washed and cleansed after any operation. Thus the objection of septic poisoning exists only in the vivid imagination of my critic. From their construction, they open any passage before them with great ease, and, as I have said before, avoid friction by presenting to the mucous surface but a small portion of the instrument at any one time, thus allowing the body of the instrument to follow with ease through any strictured canal.

From what we have heard and seen reported in the journals, Dr. Warren's instruments have proved themselves very useful in practical surgery.

Purpura Hemorrhagica.

Recent works and observations would seem to confirm the opinion of MM. Stieldorf, Wagner, Henoch, Couty, etc., on the nervous origin of certain cases of purpura. MM. Rigal and Cornil, in considering a recent case with autopsy (Société Med. des Hôpitaux), arrives at the following conclusions: 1st. Purpura hemorrhagica of gravity is a symptomatic complexus, constituted fundamentally by hemorrhages from cutaneous and mucous surfaces, and by a progressive weakness which is not always in proportion with the abundance of hemorrhage. 2d. Whatever the morbid conditions which have primarily induced purpura, there must exist some trouble of the vascular innervation to explain the hemorrhages; either an excitation of the sympathetic, or a diminution in the action of the vaso-motor centres. 3d. The alterations of the blood, and the lesions of the vascular coats, appear to be variable and not constant. And, though of importance, they are insufficient to explain the phenomena of purpura hemorrhagica.

Cases of Allocheiria.

This is the name which Prof. Obersteiner, of Vienna, suggests for the subjective error of locating an impression on the opposite side from that on which it is made. At a late meeting of the Medical Society of Vienna, he related a number of cases in illustration of this not very unusual symptom. One was of a man of thirty-five years, the subject of syphilis and consequent melancholia; another, a workman, whose spine had been injured by a falling beam; a third, a choreic girl of thirteen, etc. In all these, the sensibility, as tested by the æsthesiometer, was normal, but the seat of irritation was located on the opposite side of the body from which it was made.

Correspondence.

Pneumonia.

Ed. Med. and Surg. Reporter:—

The readers of your valuable journal, during the past few months, have seen much on the treatment of pneumonia. Views are expressed with freedom, with considerable warmth, occasionally a tinge of bitterness and ridicule, by men, some of whom are widely known. How shall the busy workers throughout our broad land get at the truth of the matter, when opinions and practices of eminent men differ so materially?

Dr. Corson, a man of eminence and experience, a bold and vigorous writer, claims that pneumonia is not a formidable disease if treated early and vigorously with the lancet. He denounces the modern methods in stinging terms, and contrasts unfavorably the results of to-day with those of our fathers.

Dr. Wile, like Saul of Tarsus, sees a great light, and becomes a vigorous apostle of the new dispensation. The claims of both in favor of bleeding, the ease with which the cases are managed, the rapidity of recovery of young and old alike, seem at first startling and wonderful.

But then comes Dr. Snow, an eminent statistician, a veteran observer, and says, May 14th, Medical and Surgical Reporter, in "Facts about Pneumonia," "The percentage of deaths from pneumonia is no greater and no less than it was twenty-five or even forty years since. There has been no perceptible change in this respect during this time." Again he says, "The debility of advanced life, and the debility of infancy, age and want of age, seem to be the most important causes of death from pneumonia. Less than one-fourth of the living population is under five and over fifty years of age, but this less than one-quarter of the population furnishes nearly three-quarters of all the deaths from pneumonia." (This reckoning for special latitude, and population of Providence.)

Again, in the number of May 7th, "B" says, "I have been in the practice thirty-seven years; half of that time have been what we call busy: have never lost a case of pneumonia, although I suppose I have had the usual proportion of that disease in my practice. If I get them before engorgement or congestion, I take pneumonia with as little concern as I do chicken pox or mild measles." Again, further on, "As for veratrum and aconite they are about as good a substitute for the lancet, in the hands of the physician, as a harrow is for a plow in the hands of the farmer." Speaking of "the stimulators," he says, "I expect all to die who are thus treated," etc.

All this suggests the old question, "who shall decide?" Where is the truth? A few comments: 1st. While our ears and our judgments should be ever open to the reception of truth from any and every source, let us not, as cool and candid physicians, be too easily influenced and carried away by the enthusiastic and extravagant claims of any one method. Cold water and ice are excellent helps in the treatment of scarlet fever, but let no one set up the claim that in that dread disease many will not die who are thus treated early and judiciously.

Give us your best treatment of diphtheria, but do not claim for it that it will cure all cases, for hundreds of us, that try it after your plan, know better. Tell us, after much experience and careful observation, what, in your judgment, is the best treatment in pneumonia, but do not add that you "take it with as little concern as you do chicken pox, or mild measles," or that "in thirty-seven years you have never lost a case." The physician has evidently seen but little of the severer forms of pneumonia in New England, in those who have passed threescore years, who can say that. And, pray, do not hold up to ridicule the practice of the hundreds of eminent and successful physicians, as honest as yourself, who think they can do better for their patients by methods differing from yours or mine. Show them the better way, calmly, considerately; do not claim too much.

2d. Is it not as well to admit the plain fact, that the gravity of the disease (in pneumonia), depends largely upon the amount of lung substance involved, the character of the disease, whether croupous or catarrhal, the age and vitality of the patient, the season of the year, etc. etc. And to admit what most of us fully believe, that many of the cases will recover without any medical treatment, and that many will die in our own time, as they have done through the past ages, under any form of medical treatment?

This query is not raised in the interests of any simple palliative, or do-nothing treatment.

It was not my purpose, in this communication, to express any preferences of my own regarding treatment; but to satisfy any curiosity on that point, I will adopt the language of Dr. J. H. Claiborne, of Virginia, in Reporter of May 14th, as my own. He did not think "we could fail to go astray if we followed the teaching of the gentlemen who always recommend bleeding, nor could we fail to go astray if we believe those who tell us never to bleed. The middle course was safest, and we should be guided more by experience than by theory. There was no one method of treatment applicable to all varieties of pneumonia."

Of the last twenty cases of pneumonia I have treated, eighteen have recovered; two have died. One of these latter was under two years of age, the other was sixty-six. The man of sixty-six I bled early in the disease, about twenty ounces. He was relieved for the time, but died about seven days from the attack, as I have known many of similar age to do. Though I cannot judge with any degree of certainty, still I hardly think the bleeding materially hastened or retarded the fatal termination. I think he would have died under any treatment. I did not bleed any one of the eighteen cases that recovered. I do not give this single case for its statistical value, for I agree with Dr. Post, "that little or no dependence can be placed on statistics," for, contrary to the old adage, "figures will lie." Still it comes in as a part of my experience.

3d. The well balanced, the useful physician, should not be an extremist. Use the knife boldly, give the heroic dose fearlessly, or the placebo conscientiously—not because any one

man vehemently recommends it as the cureall, but because, from the best knowledge you are able to gather from books and teachers, and from your own unprejudiced, conscientious judgment, you believe it best for the safety of the life committed, under God, to your care. Do it, because you would do the same if your own wife or child were the patient.

W. G. Brownson, A.M., M.D.

New Canaan, Conn.

Dr. F. M. Robertson vs. Evolution.

Ed. Med. and Surg. Reporter:—

The recent attempt of the president of the North Carolina Medical Association (see the report of his address in the recently published transactions of the North Carolina Medical Society) to bring contempt upon the doctrine of evolution and its advocates should meet with rebuke. Dr. Robertson ignores the fact that a large portion — my limited acquaintance with physicians, physicists, naturalists, etc., would lead me to say the larger portion—of those who have had a thorough scientific training have adopted in some form those theories of descent and causation which he denounces. He ignores the fact that evolution is not necessarily irreligious or atheistic, and that even Darwin claims that the utmost which he has aimed to accomplish is to explain some of the modes of operation of Deity.

The ancient notion of the origin of species by special creation has been steadily giving way to that of creation by law, and naturalists, becoming better acquainted with the fundamental unity which pervades all living things, have looked and are looking to natural causes for an explanation of the manifold and marvelous diversity which everywhere exists. An ever growing realization of the all comprehensive scope of natural law has produced this result, and Mill and Lyell were the logical precursors of Darwin and Spencer. Mill, by positing the order and uniformity of nature as the basis of his system of logic, and by formulating with clearness and precision the canons of scientific induction, made evolutionists of many of his disciples before Darwin and Wallace expounded their theory of natural selection; and Lyell, by referring all past geologic phenomena to the slow action of the same forces which are still at work over the earth's surface and beneath its crust, paved the way for Darwin and Spencer to explain the evolution of higher from lower forms of life, by agencies which are still visibly in action. That the present is the child of the past; that all things now existing sprang from antecedent causes and conditions properly called natural and adequate to their production, seems a truism to most of us.

The substance of Darwin's theory, which is so abhorrent to the North Carolina president, is briefly this: The environment of all animals and plants is continually changing; they must adapt themselves to these changes or perish. Those organisms which are best fitted to their conditions of life survive and multiply, at the expense of the others; this is "survival of the fittest," or "natural selection." This process is known to be going on at the present time, and it is legitimate to believe that it has been going on in all past time. Important modifications of structure are thus effected in the course of a few generations; these are propagated by heredity; artificial selection can produce even greater structural modifications, as every gardener and stock breeder knows. But this law of variation through adaptation to changing condition and survival of the fittest, operating through countless ages of past time, must have produced great unlikenesses, and the presumption is—supported by striking facts from every department of natural science, as experts of all kinds, who have found the Darwinian theory helpful and even indispensable, testify—that the multitudinous differentiations of existing plants and animals, known as genera, species, etc., so originated. In other words, this is the best explanation which science can at present offer of a problem which miracle has hitherto been invoked to solve. That all living things, man not excepted, sprang from one or a few primordial forms, is also a necessary part of the theory.

It is needless to say that the main thesis of Darwinism is still nothing but a hypothesis, having, indeed, a very high degree of probability, and supported by deductive evidence that is very strong. Thus the single line of argument by which Huxley connected the living one-toed genus equus with a typical five-toed ancestor common to it and other ungulate animals, showing how by progressive modifications the development has taken place, and demonstrating the successive links in the chain, carries conviction to many minds, that in at least one branch of the animal kingdom a definite pedigree, in accordance with Darwinian principles, has been established; and the inference is to me irresistible, that such has been the general course of nature in respect to animals and plants. I see no caprice in nature, but one method, one order. Men who have no strong prejudices and prepossessions, who are attentive students of nature, who are observant of the modifications now going on in living organisms in accordance with changed conditions, and who have mastered the anatomical peculiarities which constitute varieties, the more conspicuous shades of difference which constitute species etc., and who have realized the impossibility of telling, in multitudes of instances, where varieties end and species begin—there being really no hard and fast line between them—who, moreover, feel their inability to form any conception of how species could have come into existence, except as gradual or more or less abrupt modifications of preëxisting varieties, to whom, moreover, the notion of continued miracle supplementing the ordinary operations of nature is repugnant and shocking, such persons find Darwin's theory both reasonable and helpful. Yet they accept it provisionally, waiting for more light, and anxious for the truth and nothing but the truth.

In conclusion I would state the following points as pretty well agreed upon among modern scientific reasoners:—

1. We are, by the necessary limitation of our faculties, forever debarred from all knowledge

of final causes. We may learn the how, but we can never know the why.

2. We are thus shut out from all speculations as to the origin of life, etc., which are so apt to complicate investigation.

3. The faith of the age, that all things came to pass in accordance with one eternal order, which knows no caprice or chance, will abide. This divine order is the expression of wisdom, and as we have a right to believe, a plan.

Newburyport, Mass. E. P. Hurd, M.D.

Report of Snyder County, Pa., Medical Society.

Ed. Med. and Surg. Reporter:—

Society met in quarterly meeting at Middleburg, May 4, 1881. Rather a slim attendance; but the meeting was still more interesting than usual; one election for membership; one proposition for membership. At this meeting we have our annual election for officers and delegates to the Medical Society of the State of Pennsylvania. Dr. Perc. Hermann was elected President; Drs. J. F. Kanawell and I. R. Swigart, Vice-Presidents; Dr. J. Y. Shindel, Secretary; Dr. R. Rothrock, Treasurer. For Censors—Drs. J. W. Sampsell, J. O. Wagner and I. R. Swigart. Delegates to Medical Society of the State of Pennsylvania—Drs. H. M. Nipple and John Y. Shindel. Retiring President's (Dr. H. H. Bordner) address, Subject, "Society," was listened to with marked attention, and received with merited applause; on motion, Dr. Bordner was asked for a copy of the address, to be inscribed on the minutes of the Society, and to be published in one or more of the county papers, and in the Medical and Surgical Reporter, of Philadelphia. Under miscellaneous business the Secretary had read a letter from Dr. D. G. Brinton, editor of Medical and Surgical Reporter, therefore the Secretary was instructed to send an abstract of our proceedings, with a copy of Dr. Bordner's (retiring President) address. Treasurer reported a balance in treasury—all debts paid. The President-elect, in obedience to standing resolution, appointed Drs. Nipple, Swigart and Bordner as Board of Examiners for ensuing year. An operation, for the extirpation of a tumor from the neck of a young woman, was then performed—Dr. H. M. Nipple very successfully plied the scalpel. The tumor was deeply imbedded among the tendons on the left side of the neck, just under the angle of the lower jaw; was firmly attached by its base to the deep fascia; made a good recovery. The Society adjourned to meet in regular quarterly session at Middleburg, first Wednesday in August, 1881.

John Y. Shindel, *Sec.*

Scribner's Monthly's Plea for Quack Medicines.

Ed. Med. and Surg. Reporter:—

Some comment seems needed anent the peculiar argument in favor of quack medicines that appeared in a late issue of *Scribner's Monthly*. It is difficult to account for the action of the editor of *Scribner's Monthly*, himself a member of the profession, upon any other ground than one of policy. The sale of patent "cure-alls" depends upon exhaustive and ingenious advertising. Large amounts of money are yearly set aside for this purpose. The magazine or journal that champions quacks will profit largely in dollars and cents. Humanity has a weak side, and "filthy lucre" tempts the best of us. If *Scribner's Monthly* gain nothing in the matter of intelligence, it will replenish its coffers, and this fact makes logical the most chaotic and unsound deductions. There is, however, a criminal side to the question, one of which the law may well take cognizance, and the person who aids or abets the sale of a nostrum claiming to cure diseases entirely dissimilar and depending upon the most opposite pathological conditions, is a *particeps criminis*, and amenable to prosecution. In the first place, there is a well established false pretence in the claim of most advertised patent medicines, and in the second place, there is a criminality in administering narcotics, irritants and excitants in diseases the nature of which renders such administrations highly dangerous. It has happened in the experience of every practitioner to meet with infants that have been made alarmingly ill by taking cough syrups and carminatives advertised to cure, and into the compounding of which opium enters as a chief ingredient.

Very recently a case has come to my notice, of a gentleman in good standing, who had been induced to treat himself for acute Bright's disease. Death satisfied him of the fictitiousness of the Great Kidney cure, and the dealer mourned the loss of a profitable customer. The life of the man, under proper surveillance and treatment, might have been prolonged for a considerable length of time. No one in his right mind believes in a panacea for all diseases. To advance such a claim is preposterous, and stamps the advocate either as an interested party, or as insane. Science may or may not include medicine as a collateral branch, this depending widely upon the personal bias of the layman; be this as it may, it certainly will not number among its disciples those who believe in the balm of universal youth, in the indefinite perpetuation of life, or in the efficacy of certain concoctions of ignorant men who dare not state the working formulæ of their remedies upon their bottles. It is a matter of congratulation that the editor of *Scribner's* is willing to submit himself as an experiment for the good of his fellow men, and that he will find out by experience the good and the bad. The man who can thus make a common cloaca of himself, for the reception and discharge of kidney and liver cures, vegetable compounds, female curealls, etc., etc., is worthy of historic perpetuation. But a question of morality is involved in this matter. Can a magazine having the reputation of *Scribner's Monthly* afford to parade to its readers the disgusting advertisements of Dr. So and so's great remedy for gonorrhœa, nocturnal emissions, and youthful indiscretions, or Mrs. Midwife's sure and safe remedy for women, warranted to cure; or Mr. Fraud's love potions, indorsed by the leading faculties of Europe. Can we suppose that the editor of *Scribner's* does honestly believe that a remedy which will

relieve corns will also cure Bright's disease, consumption, and cirrhosis of the liver; or that a sedative for whooping cough will cure phthisis? Can any educated gentleman indorse the claims of such universal remedies? There is much of common stuff in medicine and literature; one is as much a science as the other is an art. The literateur who debases his high calling, who propagates corrupting romance, who deals in sensuality, or who prostitutes his brain for money, by pandering to the demands of pretentious advertisers, is on a par with the physician who is such only by self-election, and who has neither knowledge, character, nor diploma to give him countenance. The good physician and the honorable man of letters go hand in hand through life, despising deceit, ever engaged in advancing all that is best, noblest, and most genuine. The man of letters becomes unscientific and ignoble in the endeavor, born of ignorance, to stultify the profession of the physician and to elevate that of pretenders. The science of medicine needs no defence. It stands upon a rock, against which the winds of cavil and the empty bellowing of conceit have for years beaten in vain. It has outlived its enemies in the past, and will win over those of the present by its noble philanthropies, its brilliant results and its unceasing investigation. It is sneered at, and decried only by the sciolists who know nothing of it. Ignorance is privileged to mock at knowledge. It can afford to pass by in silence the weary, foot-sore and much abused feuilletonist, who, in the "demnition guise" of news hunting, grasps at anything sensational with a delicious unconsciousness of truth or merit. With a bottle of liver cure on one side, and "uterine regulator" on the other, writhing under the effects of cancer cures, cathartic pills and regulators, in his stomach, the brain of the champion will naturally respond in notes discordant and inharmonious. We will await with some interest *Scribner's* plea for quack literature.

Horatio R. Bigelow, M.D.

Washington, D. C.

Iodine in the Treatment of Chronic Intermittent Fever.

Ed. Med. and Surg. Reporter:—

My practice, for the most part, lies in exceedingly malarial districts, the river bottoms of Kansas. The streams are low, sluggish, with scarcely fall sufficient to carry their waters anywhere. The spring freshets frequently cause them to overflow their banks to such an extent as to engulph a great portion of the surrounding country, and a natural result is a great deal of vegetable *debris* for the scorching rays of summer to breed malarial fever. In the summer their surface is often coated with a thick, greenish scum, which only the autumnal frosts kill or winter consumes. The soil on these river bottoms is *fearfully* and wonderfully rich, an intensely black, tough compound very productive, full of moisture when the uplands are as dry as an Arabian desert, exhaling malaria of an exceedingly concentrated kind. Consequently, we have the malarial fevers in abundance, from early summer to very late fall, every variety of disease occurring partaking, more or less, of some degree of this malaria. Often, in crossing these bottoms at midday, during the hottest days of summer, I imagine I can see it, as a tangible body, floating in the air before my eyes, and at night, in fording these streams, I certainly smell it, beyond a doubt.

The ordinary forms of intermittent fever I treat with a great deal of success, by the following combination, a teaspoonful of which is taken every two hours, during both the cold and hot stages, for several days successively, omitting it only during the hours of rest at night, or when there is no recurrence of the chill after the third or fourth day of its employment. You will notice that it is a combination of the antiperiodic with a febrifuge, to meet the indications of both stages:—

℞.	Quiniæ sulph.,	℥j	
	Acid. sulph. aro.,	q.s.	
	Elix. glycyrrhizæ comp.,	℥j	
	Spt. ether. nit.,	℥j	
	Spt. mindereri,	℥vj	
	Tinct. aconit.,	gtt.xx	
	Syr. limonis,	q.s. ad ℥iv.	M.

If there is any anæmia present, as there frequently is, or if there is loss of appetite, with great debility, etc., I prescribe the following in connection with the above, a teaspoonful of which is to be taken three times daily, largely diluted with water, before meals:—

℞.	Ferri citratis,	℥iv	
	Tinct. nuc. vom.,	gtt.xxx	
	Tinct. gentian. comp.,	℥iss	
	Tinct. serpentariæ,	℥iss	
	Aquæ font.,	q.s. ad ℥iv.	M.

Occasionally cases of a rarer or more persistent form present themselves for treatment; an old hoosier, for instance, who has been in a chronic shake, perhaps, from the hour of his birth; cases in which the paroxysms occur every fourteen days, or even every twenty first day, which resist all manner of ordinary treatment, and where the spleen is as large as an average "pancake." In these cases I have met with uniformly good results from the following combination, as alterative, prescribed during the interval of attack, and up to within a day or two of the expected recurrence, when the quinine mixture given above is to be renewed, and continued until after the danger is past:—

℞.	Tinct. iodinii,		
	Tinct. sanguinariæ,		
	Tinct. ferri chlo.,	āā ℥j.	M.

Sig.—From twenty to thirty drops, in water, three times daily, after meals.

I have found this act as a cholagogue, relieving the congestion of the liver so prevalent in these cases; as a chalybeate, remedying the anæmia present; as a *splenitic*, reducing the size of the spleen materially, and as a general tonic and alterative. I have prescribed the combination for a year, or more, past, and have met with nothing since able to supersede it. For these rare forms of intermittent fever, therefore, not so rare, after all, in malarial climates, such as this.

I make no hesitation in recommending it, knowing full well, by a great deal of experience, that it will give better satisfaction than most of the remedies in vogue.

This letter was suggested by one from Dr. Samuel R. Olliphant, of New Orleans, in the Reporter for June the 4th.

Peabody, Kan. Charles H. Miller, M.D.

The Use of Quinine.

Ed. Med. and Surg. Reporter:—

I see in No. 15, current volume, where S. S. F., of Pa., puts some queries that have not been answered. 1st. To disguise the bitter taste of sulph. quinine entirely, is next to impossible, but here are three methods which greatly diminish its bitterness:—

℞. Quiniæ sulph., gr. xij
Acidi tartarici, gr. vj
Syrup aurantii corticis, f. ℥ ij M.
Sig.—One to two teaspoonfuls.

℞. Quiniæ sulph., gr. xij
Syrup acaciæ,
Aqua cinnamomi, āā f. ℥ iss. M.
Sig.—Shake well. Dose, one to two teaspoonfuls, followed by a hearty draught of water. Is nearly tasteless, the quinia salt being only in suspension, not in solution.

℞. Quiniæ sulph., gr. xij
Syrup sarsap. comp., ℥ iss
Acidi tannici, gr. ij. M.
Sig.—Dose one to two teaspoonfuls.

Now, in regard to preventing relapses in intermittent fever or ague, my experience is this: There is no known remedy, unless taken continuously for some time, that will prevent a return of the paroxysms; that is, the patient still remaining in a malarious locality. But S. S. F. will find that the disease is not so likely to recur if checked with the following:—

℞. Cinchoniæ sulph., gr. xx
Pulv. capsici,
Pulv. ext. colocynth, c., āā gr. v
Pulv. ipecac, comp., gr. x. M.
Ft. chart. No. x.
Sig.—One every two or three hours; the last one to be taken two hours before expected chill.

This prescription should be given in wafers or capsules. A purgative is hardly ever required, as the colocynth combined generally moves the bowels sufficiently; and another great advantage of this prescription is its small cost, which is quite an item to those physicians who, like myself, have to furnish their own drugs; and last, is its certainty; it will not fail as often as sulphate of quinine.

I have been fighting malarial diseases in a very malarious vicinity for the last ten years, and where the disease shows a stubborn tendency to return I prescribe the following bitter—which is bitter, sure enough, but will do the work if taken according to directions:—

℞. Sulph. cinchonidia or quiniæ, ℥ ij
Ferri cit., ℥ iij
Spiritus frumenti, ℥ ij. M.
Sig.—Tablespoonful before each meal.

This amount is generally sufficient to eradicate any case of simple ague, and has a tendency to give the patient an appetite, and remove that sallow and anæmic condition so universally found in those in whom ague has become chronic. I do not think there is any likelihood of the patient having an appetite created for stimulants, from this prescription. This is rather an expensive treatment when arsenic is so cheap, but arsenic is not so certain, nor does it meet all the indications so well; but a solution of arseniate of potassa, week about with the above, is very good treatment.

This article is a great deal longer than I expected it to be when I commenced. But if you think it would be of advantage to S. S. F., or any of the profession, publish it; otherwise, file it away in the waste basket. A. P. Levick, M.D.

Woodville, Md.

The Use of the Lancet.

Ed. Med. and Surg. Reporter:—

I have been a subscriber and reader of the Medical and Surgical Reporter for over twenty years, and consider its medical literature highly profitable to any medical man who will peruse it.

But I must confess that I have been somewhat amused, although gratified, by the correspondence which has been brought out since Dr. Corson's first article on the use of the lancet in the treatment of pneumonia. His long experience and close observation amply qualify him for saying that the lancet is the *sine qua non* as a therapeutic agent in the treatment of pneumonia.

I heartily endorse Dr. Stinson's remark (when bleeding is indicated what practitioner will refuse to resort to the lancet). Dr. Milliard, in the last number of the Reporter says, nineteen out of twenty fail to see the indication. Now, if there is that percentage of medical men who fail to see the indication, we have nineteen out of twenty utterly unfit to use the lancet if they did see the indication.

Dr. Corson tells us, in one of his articles, that some of the *great minds* of the profession are averse to the use of the lancet in their teaching. But it is for us to decide who are called to the bedside of the pneumonic patient; it is upon our shoulders that rests the responsibility of the case. And upon our judgment rests the decision whether we will use the lancet or not.

I remember, a few years ago, of meeting a homœopathic physician in the road, in my own territory, who had discarded our system and taken up the infinitesimal plan of so-called medication. He remarked, "Doctor, I want to make you a present of my lancet. I fear, when my hour of dissolution arrives, that the use I have made of my lancet will be a source of regret to me." I remarked: "You had better hold on to it. I consider the lancet the sheet anchor in congestive and inflammatory conditions of the system." A short time after our conversation this follower of Hahnemann was called to a case of cerebral congestion in my locality, and using the lancet almost to *deliquium animi*, brought about a speedy convalescence. Meeting him soon after, I

remarked, "How fortunate for you, as well as your patient, that you were in possession of your lancet." He replied, "Well, Doctor, this was a case that required prompt, decided, and immedi ate treatment." I must say that I conclude that the use of the lancet in the congestive stage of pneumonia is the *treatment*. provided we can see the *indication*. N. G. THOMPSON, M.D.

Brandywine Manor, Pa.

Skin Affections in Neuralgia.

ED. MED. AND SURG. REPORTER:—

The following case of neuralgia being so different from the usual form, prompts me in reporting it in your journal, with the hope of learning from other members of the profession of any cases similar. I am aware of the herpetic eruptions accompanying, at times, this very troublesome disease, but fail to find in medical literature any report of cases similar to mine.

Mrs. C., a young married lady—delicate in health from repeated miscarriages—gave me the history of her case before I had an opportunity of actual observation. Her statements were confirmed in about a week's time after. The pain is situated over the brow, or a little back of either wrist, and is so severe as to produce almost complete unconsciousness, lasting for an hour; then the skin over the painful part becomes red, and in from three to four days a blister, similar to one produced by cantharides, forms, bursts, and goes through the usual process of drying. After the formation of the blister the pain is re lieved, and the only annoyance is the ulcer. The duration of the attack is from five to seven days.

2010 *Arch st., Philadelphia.*

Crude Petroleum.

ED. MED. AND SURG. REPORTER:—

The many favorable reports of the efficacy of crude petroleum in chronic bronchial and lung diseases, has caused the M.D's. to give it a trial in these troubles. But I am informed that the patients soon revolt, on account of its nauseous taste and the disagreeable eructations it produces. Now, these were the troubles I encountered: in the first place, it resists almost all the formulas used in emulsifying cod liver oil. I have recently used the medicinal oil, which is purified and deodorized by throwing it as a spray into steam, and then filtering; it is pleasant, palatable, and equally as efficacous; it is simply the crude, deprived of its gases and unpleasant properties. We find it one of our most valuable medicines, in coughs, colds, asthma, and all forms of chronic lung diseases. Evidence is not wanting to prove it our most valuable palliative and cure in phthisis pulmonalis. The medicinal oil is easily emulsified. M. MILTON, M.D.

Bradford, Pa.

Correction.—On page 631, column first, line twenty-two, the paper on the Comparative Value of Atomized Fluids should have been credited to Dr. Roe, of Rochester.

NEWS AND MISCELLANY.

The Progress of Surgery.

The progress of surgery is well illustrated in the following extract from a recent lecture of Prof. Von Nussbaum, of Munich:—

That great scholar, Phillips von Walther, asserted that it was an impossibility for any man to see the deeper parts of the eye. He founded this statement upon the fact that the eye is a "camera obscura;" it is like a chamber with one window, and this window, as seen from without, appears always black, and does not permit of the remote parts of the room being seen. No one disputed this statement of Walther's; but scarcely was he laid in his grave when the ophthalmoscope was invented, and the deeper parts of the eye explored with almost mathematical exactness. The first step was to reflect light into the eye by means of a mirror; then the silvering was removed from a small portion of the back of the mirror, and so, while the rays of light reflected from the mirror lit up the interior of the eye, the structures could be conveniently examined through the transparent part of the mirror.

Dieffenbach, the bold German operator, wrote, in 1842, "It is unjustifiable to cut into the abdominal cavity in order to take out a diseased ovary. The organism will not tolerate such interference." Dieffenbach had only been a short time dead when ovariotomy produced splendid results in England; and now Keith performs fifty successive ovariotomies with only one death. A very modest calculation shows that through the ovariotomies successfully performed in England, France, and Germany, more than 30,000 years of life have been spared to the human race.

A few decades since it was considered that wounds of the intestine were invariably fatal; no one dared to put in stitches. Now the intestine is drawn out of the abdominal cavity, diseased portions to the extent of 10-12 cm. are taken away, and the healthy parts brought together. The bowel, carefully protected, is left outside the abdominal cavity for, perhaps, a few days, until it is soundly healed, and then it is returned into the abdomen. Thus it cannot now be affirmed with truth that wounds of the intestine are necessarily fatal.

It is not so very long since a suggestion made by the surgeon, Carl Theodor Merren, to remove cancer of the stomach, was looked upon as "a beautiful dream of youth." However, Professor Czerny demonstrated practically, four years ago, that a person can continue to live after the whole stomach has been removed. He cut out the entire stomach, and stitched the œsophagus to the intestine, and the digestive functions were carried on very well, and the patient had good health.

How Doctors are Made in China—The Last Resort of Medical Art among the Celestials.

Dr. Kate C. Bushnell, a lady missionary, at Kin Kiang, China, says, in a very interesting letter to the Chicago *Medical Journal and Examiner*, for May, 1881:—

The native physician of China is a member of

the literary class, and well versed in the philosophy of Confucius; of medicine he is not required to have any special knowledge. There is a law by which physicians and druggists are held responsible for errors in prescriptions, but the native never takes advantage of it.

The creation of a physician generally comes about in the following manner: A Chinaman is seriously ill; he sends for the literary relative (or relatives, as the case may be), of the family, for advice. The literary gentleman searches all the works on medicine at his disposal, and treats the patient according to directions. Should that literary man happen to be successful in his treatment, his fame is spread abroad, and ever after that he is consulted as a specialist in that particular disease. There is no doubt that many a man of the most unreliable character makes his way to the front of the medical ranks in this way, and doubtless many a life is sacrificed thereby.

The *last resort*, in serious cases of sickness, is that of administering fresh, warm, human flesh to a dying person, and it is said there are many monuments in China erected to the memory of women who have allowed themselves to be butchered for their husbands, brothers or fathers. I have yet to learn of a case where either the dying man or person from whom the live flesh was cut recovered; unfortunately, however, the *physician* usually survives the operation. Fortunately this custom is not a common one.

The Paris Municipal Laboratory.

Since October, 1878, a chemical laboratory has been in function at the préfecture of police in Paris; the city is divided into ten sections, and two expert inspectors appointed to each section; they can enter any store, or any stall in the public markets, and seize on any bad or rotten fruit, vegetables, provisions, etc., exposed for sale, or on any article of food, etc., which appears to be adulterated. Two samples of the articles seized are sent to the central laboratory for examination; the inspectors are forbidden to have any commercial dealings with the storekeepers, and are changed from one section to another monthly.

Latterly, on the earnest petition of the storekeepers, this laboratory has been opened to the public; qualitative analysis of any substance (that is the simple determination of the quality, good or bad, of the substance analyzed), is done gratuitously. For a quantitative analysis of samples of sugar, wine, beer, spices, etc., a fee of from ten to twenty francs is required. Such a service, with a similar laboratory, would be useful in our own large cities.

Opium Smoking in Persia.

A correspondent of a London paper states that he witnessed opium smoking at Kelat, in Persia, carried on in the following manner:—

The smokers lie at full length on the floor, their heads together on the same pillow, their feet outward, like the spokes of a wheel. Close to the pillow is a small circular table of alabaster, a foot wide, and raised five inches from the ground. On this is a small lamp of the same material, fed with butter. This is covered by a glass bell, about seven inches high, its edges resting on three small copper coins, so as to allow air to enter. In the top is a small hole, bound with brass. The flame comes within a couple of inches of this aperture. A piece of opium, as large as a good-sized pea, is stuck on the point of a kind of metal bodkin, and held over the flame. It is repeatedly melted and tempered before being smoked. The opium pipe consists of an earthen or metal pear-shaped bulb, about the size of a boy's peg top. In the broad end is inserted a wooden tube, ten or twelve inches long. In the side of the bulb is a very small hole. A piece of roasted opium is placed on this hole, and pierced with the bodkin, so as to allow the passage of air. The smoker holds the opium thus placed over the aperture in the glass bell and inhales the smoke, a companion all the while turning and manipulating the opium with the bodkin. After half a dozen puffs the smoker relinquishes the apparatus and sinks back in a semi lethargic state.

Vaccination Experiences.

A Detroit (Mich.) doctor, who has vaccinated over five hundred persons, reports that not more than two men out of ten have it done in a straightforward way. They hesitate, make inquiries, and postpone it a few days. One insisted upon being strapped fast to his chair while the operation was performed. Another wanted to take chloroform. A negro was one day seen to walk past the office several times. and the doctor finally stepped to the door and asked him if he wanted to be vaccinated. "'Deed, sah, dat's what I cum for," he replied, "but de werry minit I turned dat corner de blamed thing quit aching!" As a rule, the men, when they feel the lancet, cry "Woosh!" or "Thunder?" The women cry "Ouch!" generally, but now and then one screams "Oh, Lordy!"

Enforced vaccination in England has led almost to a riot in the coal and iron district near Manchester. The report is now current that the Government find the population of the country is increasing too rapidly, and are determined to destroy as many as possible of the rising generation. Ready credence is given to other stories of the most monstrous character, and the people, in fact, are reduced to that state of panic in which they will lend an ear to any story, however absurd.

Centennial Meeting of the Massachusetts State Medical Society.

The Medical Society of Massachusetts held its Centennial Anniversary, commencing Tuesday, June 7th, and occupying that and the following days. The programme embraced an oration by Dr. S. A. Green, in Sanders' theatre, and one by Dr. John Collins Warren; a dinner with President Elliott and the Fellows of Harvard University; an excursion down Boston Bay; a reception by the President, and other pleasing features. The attendance was large, numbering in all about a thousand, and there were a number

of invited guests, both from the non-medical citizens and from the profession in other States. Most of the addresses were historical in character, setting forth the early history of the Society, and the condition of the profession in Massachusetts in the olden time.

The British Contagious Diseases Acts.

The Report of these acts, which aim at the registration and examination of prostitutes, has been published for the year 1880. It sets forth in clear and unmistakable terms the advantages, both to the public and to this class of women, of such medical and police inspection. After a full analysis of the Report, the *British Medical Journal* says, editorially:—

"From all this, it is evident that the repeal of the acts would be most disastrous to the various districts which have the advantage of their beneficial working; while nothing could be more desirable than their extension, at least to all the garrison towns and naval seaports to which they have not as yet been applied."

There is not a medical journal in Great Britain but entertains and expresses similar sentiments; while in the United States the MEDICAL AND SURGICAL REPORTER continues almost alone in its advocacy of the introduction of a similar system here.

Comparative Mortality of 1881.

The *Sanitary Engineer* contains a comparative statement, prepared from figures in the posses sion of the National Board of Health, showing the comparative annual rate of mortality per 1000 of population, from diphtheria, scarlet fever, measles and smallpox, based on the returns for the first quarters of 1880 and 1881, of five leading cities:—

	1880.	1881.	Inc.	Dec.
New York	2.12	4.18	2.06	.....
Brooklyn	2.42	4.07	1.65	.....
Philadelphia	1.57	4.25	2.68	.....
Cincinnati	1.68	1.21	.....	0.48
Chicago	3 86	2.74	.....	1.12

These figures show that while the death rate of Philadelphia is below that of some other American cities, it is increasing at a frightful rate.

Color Blindness in Pilots.

In conversation on the subject of color blindness, Supervising Inspector General of Steamboats Dumont says:—

"Every day develops additional proof that it is necessary that pilots of steam vessels and engineers of railroads should be most carefully examined for color blindness by experts. The latest case bearing on this subject that has been brought to the attention of the authorities here is that of the pilot of the City of Austin, who, through mistaking the color of the buoys in the channel, lost the vessel in the harbor of Fernandina, Fla., on the 24th day of last April. Owing to the fortunate mildness of the weather no lives were lost, but the estimated loss on vessel and cargo is $200,000.

Enlargement of the Jefferson Medical College.

The increase in the number of students at Jefferson Medical College, this city, has rendered an extension of the main building necessary. The Tenth Street front will be built up in pressed brick, even with the street line, giving additional seating capacity in the amphitheatre for one hundred more students. The present dissecting room will be transformed into a laboratory, and an additional story will be erected on the western end of the structure, to be used for dissecting purposes. The interior of the building will also be thoroughly renovated, and when the improvements are completed, which will be by September 1st, the building will be practically a new structure.

A Prophetic Joke.

A correspondent of the Louisville *Medical News* states that he was recently called to see a very intelligent lady, who was pregnant, and greatly troubled with nervous vomiting. She ascribed her gastric symptoms, in a jocular way, to "being *enceinte* with twin boys, and, you know, boys will quarrel."

He gave her one drop of wine of ipecac three or four times a day, which afforded her decided relief during the succeeding three weeks of its use, at the end of which she was delivered of two fine boys. The diagnosis suggested by her wit had proved correct.

The National Board of Health

The annual meeting of the National Board of Health closed its sessions in Washington, June 3d. The following officers were elected for the ensuing year: President, James L. Cabell; Vice President, John S. Billings; Secretary, Thomas J. Turner: Executive Committee, P. H. Bailhache, J. S. Billings, J. L. Cabell, S. F. Phillip, S. Smith, T. J. Turner.

Patent Medicines in Great Britain.

Increasing intelligence does not seem to diminish the sales of patent medicines. The English statistics show that, while in 1844 the State tax amounted only to $150,000 per year; at the present time it is nearly one million dollars a year. It is said, too, that they are bought rather by the middle and upper, than by the poorer classes.

The Washington Training School for Nurses

Held their graduating exercises in the Congregational Church, Tuesday evening, the 24th of May. The President, Dr. Toner, delivered an address on the organization and management of the Society, and its methods of instruction. A number of other addresses were also made.

Lactopeptine in Cholera Infantum

Now that the sickly period of the year for infants is approaching, it will not be inappropriate

to recall to our readers the various testimonials to the value of lactopeptine in this complaint. Administered at a sufficiently early stage it modifies the secretions promptly and favorably, and leaves no after effects of an unpleasant character.

The Yellow Fever.

A few cases of yellow fever have been reported from Havana. Telegrams from the City of Mexico report that, owing to the prevalence of yellow fever at Vera Cruz, the Mexican railway company has put on a special train on the days of the arrival of steamers, to take passengers direct to Orizaba.

Personal.

—Dr. J. D. Littlefield, of Titusville, Pa., has removed to Boston, Mass.

—Dr. J. Marion Sims, who has been passing some months in Florida, has returned, greatly benefited in health.

Items.

—Trouble over the clause providing for the appointment of a female physician in the Insane Hospital at Warren, Pa., nearly defeated the bill, in the Legislature, for the organization of that Institution.

—The State Medical Society of Wisconsin met June 7th, in Milwaukee, with a full attendance. The President was Dr. Ira Manley, Jr., who delivered an address on the Influence of the Mind on the Body.

—A bill for the prevention of bad plumbing, and which requires all plumbers in New York City and Brooklyn to be registered, has become a law. Its principal feature is the requirement of the approval of the Board of Health for drainage and plumbing in the future.

—Diphtheria is epidemic in Ludington, Michigan. One hundred and twenty children have died there recently of that disease, out of a total population of four thousand. The schools are closed, and all the infected houses quarantined by special policemen.

OBITUARY NOTICES.

DR. GREENSVILLE DOWELL.

This well-known surgeon, who for the past fifteen years has been Professor of Surgery in the Galveston Medical College, and editor of the Texas *Medical Journal*, died in Galveston, June 9th, after five days' illness. He was born in Virginia, September 1, 1822, and received his degree of M. D. from the Jefferson Medical College, in 1847. He practiced first in Mississippi, then at Memphis, and in 1853 removed to Texas, where he finally established himself. During the war he was surgeon in the Confederate Army, and for two years was in charge of the Galveston General Hospital.

Dr. Dowell was a frequent contributor to medical journals, and wrote two separate volumes—one on the Radical Treatment of Hernia, the other on Yellow Fever and Malarial Diseases. He had an extensive acquaintance with modern languages, and as a lecturer was fluent and lucid. The radical operation for hernia which he devised gave excellent results in his hands, and has been adopted and successfully carried out by a number of surgeons, especially in the Southern States. Personally Dr. Dowell was a gentleman of agreeable manners, great kindliness of heart, and of pleasant conversation. He will be widely regretted.

DR. HUGH LENOX HODGE.

Dr. Hodge died of pneumonia, on June 9th, at his residence in Philadelphia, closing at a too early age a career of exceptional promise. He was born here, July 30th, 1836, his father being the late Professor Hugh L. Hodge, of the University of Pennsylvania. He graduated from the medical department of the University of Pennsylvania in 1858, when he became resident physician of the Pennsylvania Hospital, which office he retained until the spring of 1860. In 1861 he was appointed Demonstrator of Anatomy in the University of Pennsylvania, and commenced in the same year the instruction of private classes, on Chestnut street, between Ninth and Tenth streets. Shortly after he began a series of lectures on Anatomy and Operative Surgery. In 1870 he was appointed Demonstrator of Anatomy in the University, and about the same time became Attending Surgeon at the Children's Hospital. When the Presbyterian Hospital was opened, in 1872, he became Attending Surgeon at that institution.

Dr. Hodge wrote many important papers for the medical press. Some of his subjects were: "Metallic Sutures," "Tracheotomy in Croup," "Drainage by Solid Metallic Probes," "Deformities of the Hip," "The Construction, Ventilation and Hygienic Management of Anatomical Rooms," etc. His principal attention had been given to surgery, and during the war he was professionally engaged in the Army of the Potomac, and at various military hospitals. His personal character ranked among the purest and the best, and a wide circle of families to whom he was medical adviser will regret his loss, as well as the many personal friends to whom he was dear.

MARRIAGES.

BERGHAUS—SOHOENBEEK.—In New York, May 7th, by the Rev. Mr. Mohn, Alexander Berghaus, M.D., and Annie Sohoenbeek.

LEWENBERG—LEE.—On June 2d, 1881, by Rev. James Shrigley, J. F. Lewenberg, M.D., and Annie E. Lee.

DEATHS.

BOYD.—At Albany, N. Y., on May 10th, James P. Boyd, M.D., in the seventy-eighth year of his age.

EVANS.—At Penrhyn, Lower Merion, Montgomery county, on Sunday, May 22d, 1881, Dr. Edward Cadwalader Evans.

HODGE.—In this city, on Friday, June 10th, H. Lenox Hodge, M.D., in the forty-fifth year of his age.

O'DANIEL.—At Wilmington, Del., on the 1st instant, Dr. John P. O'Daniel.

WILMARTH.—On Tuesday, June 7th, at his residence, in East Orange, N. J., Frank Wilmarth, M.D.

PULMONARY GYMNASTICS; OR, FORCED RESPIRATION IN THE TREATMENT OF SO-CALLED WEAK LUNGS, ATELECTASIS, PHTHISIS, ETC.

BY T. C. SMITH, M.D.,
Of Aurora, Indiana.

Every practitioner of medicine of any considerable experience has often found himself confronted by patients complaining of general weakness, dyspnœa after moderate exercise, a feeling amounting to soreness, or dull pain within the lungs, perhaps dull intercostal pains. Attending these symptoms there is often general lassitude and melancholic expressions. Physical exploration may not, and very often does not, develop any evidence of disease of the lung tissue. Often there will be found seeming emphysema; sometimes this is real. When so, it is due to the destruction of the walls of the cells, resulting from a subacute inflammation or hypostatic stasis in a circumscribed tract of lung tissue. This condition, we think, can be produced by partial or complete disuse of a portion of the air cells, resulting from bronchial catarrh, especially the chronic form, and from lobular pneumonia, tubercular deposits, and, in otherwise healthy lungs, by long continued imperfect or incomplete respiration. This pathological condition once set up, the epithelium of the air-cell walls loosen their attachment to their walls, leaving them denuded of their natural protection. Under the influence of the decomposing débris of detached epithelium, the cell walls often break down, as in ordinary inflammation, and several cells are merged into one, producing cavities, small in extent, but as real as in phthisis. We think such a condition may in time be produced by imperfect respiration, which leaves these air cells unused until circumscribed disease results.

It has been a constant observation for many years, in my experience, that a very large proportion of persons complaining of the symptoms heretofore named have been men of sedentary habits, and women who labor while seated, and perhaps, while bending over their work. Among men affected thus, are tailors, teachers, students, scriveners and book-keepers, and sewing-women, milliners, etc., among the females. This difficulty has been found to be especially present among those confined closely at their labors many hours in the day, and who take little or no active exercise, outdoors or in. We have often noticed that persons affected with the symptoms named have made rapid improvement when taken from their sedentary labors and set at active out-door employments. It was a common observation, during the late war, that men of indifferent health, anæmic, thin in flesh, almost cadaveric in appearance, who went from store and shop to the open air, active drill, march and campaign, with their hardships and exposures, not only endured them well, but very often improved greatly in health under them. Of course no one will claim that all resulted thus. Nor will it be claimed that all were affected with so called weak lungs. But most were of those who had practiced, unconsciously, imperfect respiration while at their in-door employments. If, in these cases, there is any hereditary tendency to phthisis, the gravity of the symptoms is greatly increased, and, unless overcome, will be likely to lead to serious results.

My attention was called to this condition of lung tissue very early in my practice, now nearly twenty years ago, by the case of a young student, who was of healthy physique, good habits, and of healthy parents. He was a hard student, and applied himself to his books ten to fourteen hours per day. He complained of dyspnœa on slight exercise, pain in the chest, of intercostal pain, had dry, troublesome cough, general lassitude, and disposition to melancholia; thought he had some form of "heart disease." Of course, he was over-worked. Rest was ordered, out-door exercise and good diet. After about two weeks he had improved in general comfort and strength, but the pulmonary symptoms were quite the same. He was then directed to make deep and prolonged inspirations and forced expirations many times every day. The method was as follows: He was to place a small tube between his lips—a common quill or toothpick answers very well—and *breathe exclusively through this*, both by inspiration and expiration. He was to be slow in both processes, and to make the utmost effort at deep inspiration and forced expiration. The forced expiration is quite as essential as forced inspiration. About every third respiration he was directed to quickly withdraw the tube from between the lips, *when the lungs were thoroughly filled*, and to hold his breath as long as he could, without distress. This simple process was to be repeated six to eight times every twenty-four hours, and he was to take a dozen deep inspirations in this manner at each time of repetition. He at once experienced relief, and he soon not only was rid of all chest trouble, but improved more rapidly in general health. Physical examination at no time showed any real disease of lung tissue in this case. This young man continued to practice this during his years of student life, and acquired the ability to effect a difference of five inches in the measurements of his chest, as between forced expiration and inspiration; and could, after taking a few deep inspirations, hold his chest full of air for a full minute, without distress.

There is, perhaps, no simple expedient to which all sedentary persons, especially students, could so easily resort habitually, that would be likely to yield such good results in keeping them clear of so-called weak lungs and uneasy chest pains, as this one. It will at once be seen that it will cause a more perfect oxygenation of the blood, and thus rid the economy of the accumulated excess of carbonic acid gas, and enable other organs than the lungs to carry on their functions better, by means of a purer blood and better assimilation. Any one has but to practice these deep inspirations a few times every day, to note the fact that there follows almost every effort a feeling of general comfort and slight exhilaration. I could relate many cases like that above, but I turn from these to a typical one in the first stage of phthisis pulmonalis.

G. H., æt. 26, of spare build, nervo-lymphatic habit, farmer, living among the hills in a naturally healthy section. Several of his brothers had died of phthisis. I found his respiration loud and rasping, bronchial, the chest flat, right apex somewhat sunken, considerable cough, prolonged expiration, marked dullness over right lung, upper lobe; he had lost several pounds in weight during the autumn and early winter, had nocturnal sweating, and felt very much prostrated. His symptoms and physical condition, in short, were such as to warrant a diagnosis of phthisis in the first stage. This case presented itself to me in February, 1880. I gave him an ordinary expectorant for his cough, and a tonic of iron and quinine. With these there was belladonna added at bedtime, to control his nocturnal sweating. He was carefully instructed as to the method of forced inspiration and expiration, and urged to carry it out faithfully for many months to come. I did not see him again for two months. He then stated that he improved rapidly in strength under the use of the tonic, and that his cough soon ceased to annoy him. He referred to the forced respiration as a means of relief new to him, and that it had certainly proved of great value. He no longer felt any uneasy aching within the chest, nor any dyspnœa; could breathe deeper, expand his chest more fully; has less flatness of breast and less dullness on percussion. One year later he confirmed this statement, adding, with special stress, that the forced respiration had certainly been a great benefit to him, in the way of keeping him free from cough, short breathing, and pain in his lungs.

It is not claimed that this will cure phthisis in its early stage, but it may be made a valuable means of relief in connection with other remedies. It will often be found that in many cases where a condition of atelectasis is present, from bronchial catarrh, or following lobular pneumonia, forced inspiration will be the means of opening up the closed bronchial tubes and air-cells sufficiently to cause a removal of the trouble. By this means the decomposing debris of detached and locked-up epithelium can be removed, and the diseased lung tissue treated to the pure air needed to restore it, through

reparation, to a condition of health. Where the thickened mucous membrane of the diseased bronchia causes atelectasis of any portion of the lung, forced inspiration will often open this up, and the collapse of lung tissue will disappear, or enclosed foul air will be exchanged for that which is pure and wholesome.

It is almost needless to add that medicated vapors can by this same method be carried to all parts of the lung where it is possible for air to find access. The wise use of such vapors will often greatly aid in the treatment of many of these numerous cases. These statements are given, hastily, it is true, from an experience running over a sufficient number of years to have made many observations. And I can but say that in many forms of pulmonary disease it will often be found more beneficial than may at first seem apparent. Of course, the exercise should be performed in healthy air. It cannot be expected to permanently relieve the symptoms named when these depend on cardiac lesions, or extensive pulmonary lesions of large extent, but even there improvement may often be expected.

Medical Societies.

RHODE ISLAND STATE MEDICAL SOCIETY.

The 70th Annual Meeting of this Society was held in Providence, June 8th. Dr. Charles O'Leary, the President, in the Chair. Reports were made by the Treasurer, the Board of Censors, the Trustees of the Fiske Fund, the Library and Publishing Committees.

EXPERT TESTIMONY.

Dr. Job Kenyon, from the Committee on Expert Testimony, submitted a report. Allusion was made to the presentation of the petition to the legislature, in 1879, asking that relief might be granted to physicians called to testify as experts; the drafting of an act embracing the relief asked for and its reference to the Judiciary Committee, and the appearance of the committee before the legislative committee. The committee recommended to the Society that the individual members, when called as experts, refuse to testify (in private cases), and thus protect ourselves from what we believe are unjust encroachments on our profession. The committee further recommended that continued efforts be made to induce the legislature to pass an act similar to that recommended in the second section, regulating expert testimony when given in the higher State courts, and that the present committee be discharged and a new one appointed for the purpose.

Dr. Ballou, of Woonsocket, moved that the report be received, with the exception of that clause in reference to the discharge of the committee. The motion of Dr. Ballou prevailed, and the committee were continued.

Dr. L. F. C. Garvin, from the committee, offered the following resolution, which was unanimously adopted:—

Resolved, That the Fellows of this Society, in serving as witnesses for parties other than the State, refuse, both when summoned and while upon the stand, to give expert testimony without suitable additional compen ation.

ELECTION OF OFFICERS.

The election of officers was then proceeded with, and Dr. Charles O'Leary and Dr. Job Kenyon were candidates for the presidency. Dr. O'Leary received the majority of the votes, and declined the honor, but was induced to retain the office, the Society voting unanimously to that effect. The election then resulted as follows:—

President—Charles O'Leary, Providence.

First Vice President—Job C. Kenyon.

Second Vice President—O. C. Wiggin, Providence.

Recording Secretary—George D. Hersey, Providence.

Correspondiny Secretary—Edward M. Harris, Providence.

Treasurer—Charles H. Leonard, Providence.

Board of Censors—David King, Newport; Ariel Ballou, Woonsocket; Otis Bullock, Warren; J. H. Eldridge, Greenwich; George B. Baker, of Providence (receiving 32 votes to 24 for W. O. Brown); J. W. C. Ely, Lloyd Morton, S. S. Keene.

Publication Committee—H. G. Miller, R. F. Noyes, G. W. Porter.

Library Committee—T. Newell. H. G. Miller, G. D. Hersey, O. C. Wiggin, G. W. Porter.

Dinner Committee—C. H. Leonard, A. G. Browning.

Audit Committee—T. Newell, C. W. Fabyan.

The following gentlemen were elected fellows of the Society:—

Stephen Hull Sears, M.D; Josephus Corma Maranda, M.D.; Alvin H. Eccleston, M.D.

THE PRESIDENT'S ADDRESS.

President O'Leary then delivered an address upon the "Use and Abuse of Hospitals and American Charities," and gave an interesting historical sketch of the rise and growth of the hospital, the predominating spirit which has governed its success from the past ages down to the present time, until its attainment of its proud and honorable position.

At the close of the address a vote of thanks was given to President O'Leary for his admirable and interesting effort, and it was referred to the Publication Committee.

The meeting then adjourned, and the Society repaired to the City Hotel, to partake of the annual dinner.

BURLINGTON COUNTY (N. J.) MEDICAL SOCIETY.

The Burlington County New Jersey Medical Society held its regular quarterly meeting last week, at Moorestown. The able historian of the Society, Dr. Joseph Parrish, of this city, delivered an address upon the "Geography of Malaria." Dr. Parrish holds that the theory of marsh miasm is not vindicated by the experience of residents

in most of the seaboard counties of this State. No malarious diseases seem to be indigenous to the salt marsh, cranberry bogs, shore springs and cedar swamps, which cover thousands of acres of New Jersey; indeed, those regions are noted for their healthfulness. It is equally true, he argues, that in elevated regions, which are free from contaminated or obstructed water courses, where there is no marsh or accumulated organic matter undergoing decay, fevers of a periodic nature are common. Indeed, they occur at all seasons, and in almost every climate, on the open sea, in the sandy desert and on the fruitless rock.

External Use of Jaborandi in Mammary Inflammation.

The following case is recorded by Dr. H. B. Stehman, in the Lancaster *Med. Soc. Trans.*, April, 1881.

Mrs. K., multipara, on the sixth day after confinement had much pain in the left breast, which had become hard and swollen, with considerable fever, pain in head and back. In examining the breast, I discovered a large cicatrix, and on inquiry learned that in her second confinement she had suffered in a similar manner; that the inflammation went on to suppuration, and finally the breast was lanced. I prescribed a diaphoretic mixture, and locally used a poultice composed of two parts flaxseed meal and one part crushed jaborandi leaves. The leaves were infused in a quantity of hot water necessary to make the poultice of proper consistency, in order that the active properties of the jaborandi might be more thoroughly mixed with the meal. These poultices were continued for forty-eight hours; at the end of the first twenty-four the breast was flaccid, the swelling reduced and the pain had disappeared.

There was no milk drawn from the breast in the interim, and the most gratifying feature was the fact that the engorged breast was entirely relieved.

At the end of the second day the treatment was discontinued, the milk flowed freely, and the mother nursed the child from this breast as well as from the other. I have used this treatment in a number of similar cases since then, and have never seen it fail, if adopted before suppuration had set in.

I have used these poultices in the inflammatory stages of buboes, and succeeded in preventing suppuration.

In mumps this treatment proved equally gratifying.

The Application of Galvanism to the Bladder.

Mr. R M. Murray says, at the close of an article in the Edinburg *Medical Journal*, April, 1881:—

Before concluding this paper I may be permitted to offer one or two hints as to the mode of conducting the application of galvanism to the bladder. The instructions given in books are not sufficiently explicit as to some precautions, and my experience in the treatment of several cases last winter, in the wards of the Royal Infirmary, under the charge of Professors Sanders, Grainger Stewart, and Annandale, and in the private practice of Dr. Croom, may enable me to offer some suggestions for the benefit of any one who may think of applying it.

In the first place, the current to be employed must be of the very gentlest at first, and the increase must be slow and gradual. The bladder is often morbidly sensitive, and anything like a violent current or shock may produce very acute cystitis. In my experience it has done so on one occasion, when, through a fault in the battery, the zinc plate suddenly slipped entirely into the fluid.

In order to avoid any risk at first, it is a safe plan for the operator to pass the current through his body, which can be done by seizing one handle with the left hand and passing the moistened right hand over the back and abdomen of the patient, the other terminal being in the bladder. By pressing the hand firmly or lightly the current can be increased or diminished, and its strength is accurately estimated by the operator, while the patient is gradually accustomed to an increased power of the current. The current should be applied for ten minutes at first, and this gradually increased as the patient can bear it. It is well to have a little urine in the bladder; it serves to diffuse the stimulus, and is more agreeable to the patient than when the bladder is empty. And a final precaution must not be forgot, and that is, to stop the current before withdrawing the bougie, otherwise the most acute pain will be induced in the course of the urethra, which often remains for a considerable time.

An Important Modification of the Ordinary Anæsthetic Methods.

The *Revue de Chirurgie et Arch. Méd. Belge* observes that Messrs. O. de Stefanis and Vachetta, convinced of the dangers attending the use of anæsthetics—statistics showing that with chloroform there occurred one death in 2873 cases, with ether, one in 23,204, while bichloride of ethylene showed one death in 5000 cases—propose a modification, which has already given them excellent results, both upon men and animals.

It was suggested to them by this consideration; that death being caused by cerebral anæmia or cardiac paralysis, anything that could induce a congestion of the nerve centres and excite the heart would help in controlling the

noxious effects of the anæsthetic agent, without diminishing insensibility. For this purpose they make use of alcoholics; we shall not repeat here their experiments upon dogs and rabbits; it is more interesting to note the method recommended to bring on inebriety in the subjects to be anæsthetized.

In place of prescribing a strict fast, they advise patients to eat a light breakfast of crackers or bread, and according to age, sex, strength, and the habits of each one, to drink a certain quantity of some light wine, like claret. This quantity may vary from 100 to 200 grams. (f. ʒ xxv–f. ʒ l.) Those accustomed to alcohol may besides take a little brandy. When the heart is found to be sufficiently excited, the inhalation of ether or chloroform may be proceeded with.

Experience proves that under those conditions complete anæsthesia is obtained in a few minutes, by the use of from five to ten grams (♏ 75 to 150), of the anæsthetic agent.

Judging from their first experiments, the authors believe themselves warranted in drawing the following conclusions:—

When a dog is prepared for anæsthesia by the aid of Marsala wine, he is less sensitive to the effects of ether or chloroform, but the dangers inherent to anæsthesia are reduced If the animal is inebriated, insensibility and muscular relaxation are longer in showing themselves.

If anæsthesia is repeated at short intervals, the subjects become less liable to its effects. Alcoholic intoxication, both in man and in animals, does away with all danger arising from cardiac paralysis, or cyanosis due to vasomotor palsy; no emesis has ever been noticed.

A man slightly under the effects of alcohol yields more readily to the influence of an anæsthetic; a lesser quantity is required to induce sleep.

In no case has sleep been followed by such marked secondary phenomena, like vomiting, prolonged somnolency, and falling temperature, as happen with patients who have been put to sleep by the ordinary method.

Reviews and Book Notices

BOOK NOTICES.

A Treatise on the Diseases of the Nervous System. By William A. Hammond, M.D., Surgeon-General U. S. Army (Retired List); Professor of Diseases of the Mind and Nervous System in the Medical Department of the University of the City of New York, etc. With one hundred and twelve illustrations. Seventh Edition, Rewritten, Enlarged, and Improved New York: D. Appleton and Co., 1, 3 and 5 Bond Street. 1881. 8vo. pp. 929. Price, Cloth, $6. Sheep, $7.

During the five years which have elapsed since the publication of the sixth edition of this standard work on diseases of the nervous system, investigations in this special department o pathology have been pushed with remarkable activity and vigor, both in this country and abroad. New and improved instruments are constantly coming into use, enabling the physician to interpret accurately symptoms which formerly were obscure, and consequently make his treatment more rational. Among those who have contributed largely to this rapid advancement, few are more widely known than Dr Hammond. and we feel assured that this new edition. which has been thoroughly revised and enlarged by the addition of much that is new, will receive a hearty welcome from the medical profession on both sides of the Atlantic. The author is a concise writer, who never wastes any paper, and he has, as he says himself in his preface, views of his own on every disease considered, and he is not afraid to express them; in short, the work is largely the result of his own observation and experience, though the labors of others are by no means ignored.

After an introductory chapter on the instruments and apparatus employed in the diagnosis and treatment of diseases of the nervous system, he divides the contents of the book into six sections, in which are considered, séverally. D seases of the Brain. Diseases of the Spiral Cord, Cerebro spinal Diseases, Diseases of the Peripheral Nervous System. Diseases of the Sympathetic Nervous System, and Toxic Diseases of the Nervous System. Among the chief additions which this edition has received, we notice that the chapter on cerebral congestion has been considerably enlarged, and a chapter on myxœdema, and others on syphilis of the brain, the spinal cord and the nerves, have been introduced; also a chapter on the symptomatology of cerebral and cerebellar lesions, and a new section on diseases of the symp thetic nervous system, which is well worthy of being carefully studied. Material additions have also been made to the chapters on locomotor ataxia, progressive facial atrophy, chorea, epilepsy, neuralgia and others. The chapters on insanity have been omitted, the author being at present engaged in the preparation of a special treatise on this subject. As a proof of the universal favor with which this work has been received on the Continent of Europe, we learn that in addition to the French translation already in existence, an Italian translation, under the editorial supervision of Professor Diodato Borelli, of the Royal University at Naples, is now going through the press.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SPECIAL BONUS TO SUBSCRIBERS.

Desiring to offer special advantages to the patrons of this Journal, we offer to mail to all *paid-up* subscribers any of our publications at *twenty per cent. discount, postage prepaid.* We append a list of the most recent, with regular price and price to subscribers.

HALL.—DIFFERENTIAL DIAGNOSIS. Edited by Dr. Frank Woodbury. Second edition. $2.00. To Subscribers $1.60.

SEILER.—MICROSCOPICAL TECHNOLOGY. $1.00. To Subscribers 80 cents.

GUBLER.—PRINCIPLES OF THERAPEUTICS. Translated by Dr. Halloran. $4.00. To Subscribers $3.20.

GOODELL.—LESSONS IN GYNECOLOGY. Second edition. $4.00. To Subscribers $3.20.

MORTIMER—GRANVILLE.—COMMON MIND TROUBLES. $1.00. To Subscribers 80 cents.

NAPHEYS.—MEDICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

NAPHEYS.—SURGICAL THERAPEUTICS. Seventh edition. $4.00. To Subscribers $3.20.

ATKINSON.—GYNECOLOGICAL AND OBSTETRICAL THERAPEUTICS. $3.00. To Subscribers $2.40.

ATKINSON.—HINTS IN THE OBSTETRIC PROCEDURE. Second edition. $1.00. To Subscribers 80 cents

Full catalogue on application.

THE IMPROVEMENT IN MEDICAL LITERATURE.

The full Index which we give in this number crowds out much of the reading matter we are accustomed to furnish. The value of an Index, however, is too well known for its intrusion to require any apologies. It is an indispensable feature in every well-edited book or periodical.

We may take occasion in this connection to remark on the manifest improvement, both in the contents, appearance and manufacture, of medical books and journals, within the last ten or a dozen years. This is visible, both in the care exercised in editing, in the more scientific tone of the contributions, and in the paper and printing. A gentleman who had been going over all the French medical journals he cou'd lay his hands on, last winter, mentioned with surprise the fact that not one of them equals, in quality of paper, neatness of presswork and variety and value of contents, the MEDICAL AND SURGICAL REPORTER.

Even the best English journals, such as the *Lancet*, the *Medical Times and Gazette*, the *British Medical Journal*, and the *Medical Press and Circular*, compare unfavorably, both in paper and presswork, with the REPORTER, while not one of them is bound; and while in contents some of them are more lengthy, the excess is made up of the merest local discussions and obvious "padding."

Yet it is true that both in France and England everything re'a ing to the manufacture of a journal is cheaper than in the United States; paper, setting the type, correction, presswork, are all at materially lower prices. The fact is, that the American public is more requiring than that of the Old World; it demands more fr quent changes, more constant improvements, a perpetual progress; and it is right in doing so. This demand is a constant spur to strive after better things and to seek on all sides to obtain the most desirable.

Aware of this, we shall hereafter, as in the past, spare no pains to make the REPORTER more valuable to readers, by making it more costly to ourselves, every year. Both in respect to the details of its manufacture and to the quality of the

material, it shall not abate its just claim to equal any journal of its class anywhere published.

Notes and Comments.

Impetiginous Eczema of the Scalp.

The *Journal des Sci. Med.* states that M. Vidal recommends the following treatment: Lotions with a decoction of walnut leaves. Frictions, morning and evening, with a weak glycerole of cade, thus prepared:—

Glycerole of starch, 30 grams (℥ viiss),
Oil of cade, 5 grams (grs. 75).

If too great an irritation is produced by these frictions they should be discontinued for a time. If, as is often the case, the patient is of weak constitution, this local medication is to be further assisted by a general treatment, consisting of iodide of iron, hop tea and sulphurous baths.

In another, and quite different form of eczema, Mr. Vidal prescribed the following glycerole:—

Glycerole of starch, 30 grams (f. ℥ viiss)
Tannin, 2 " (℥ ss)
Calomel, 1 " (gr. 15.)

This was in the case of a strong and vigorous, but arthritic, patient, in whom an eczema of both arms, although, since some time past, treated by envelopment in India rubber, remained in a stationary condition. When eczema has reached that stage a glycerole of tannin and calomel may induce a somewhat rapid modification of the lesion.

Rectal Touch in Coxalgia.

M. Cazin read a report on this subject before the Académie de Médecine April 26th.

This mode of investigation, formerly reserved for exceptional cases, where voluminous intra-pelvic abscesses were suspected, should become an integral part of the examination of all cases of coxalgia, whether with or without suppuration. The symptoms observed in this way consist in pain on pressure over the post-cotyloid surface; engorgement of the intra-pelvic ganglions; augmentation in volume of the osseous surface; depression, flexibility, mobility, destruction or perforation of the post-cotyloid surface; boggy feeling of the soft parts and pelvic abscesses of different volumes; communication between pelvic abscesses of small volume and external fistulæ. These pelvic abscesses are often unique, and are found in cases of coxalgia regarded as without suppuration. So that every attempt at forced straightening, resection, etc., should be preceded by minute exploration of the portion of the pelvis corresponding to the bottom of the cotyloid cavity.

Action of Bromides in Epilepsy.

Dr. A. Hughes Bennett (Edinburgh *Medical Journal*, March, 1881), in an interesting paper, sets out the following conclusions: 1. In 12.1 per cent. of epileptics the attacks were completely arrested during the whole period of treatment by the bromides. 2. In 83.3 per cent. the attacks were greatly diminished, both in number and severity. 3. In 2.3 per cent. treatment had no apparent effect. 4. In 2.3 per cent. the number of attacks was augmented during the period of treatment. 5. The form of the disease, whether it was inherited or not, whether complicated or not, recent or chronic, in the young or in the old, in healthy or diseased persons, appeared in no way to influence treatment, the success being nearly in the same ratio under all these conditions. 6. In 66.6 per cent. there was no trace of bromide poisoning. In the remaining 33.4 per cent. this was observed in varying kinds and degrees; but in no case to any serious extent—namely, physical weakness in 28.5 per cent.; mental weakness in 18.8 per cent.; and the so-called bromide eruption in 16.6 per cent.

Lemon Juice in Diphtheria.

Dr. J. R. Page, of Baltimore, in the New York *Medical Record*, May 7th, 1881, invites the attention of the profession to the topical use of fresh lemon juice as a most efficient means for the removal of membrane from the throat, tonsils, etc., in diphtheria. In his hands (and he has heard several of his professional brethren say the same) it has proved by far the best agent he has yet tried for the purpose. He applies the juice of the lemon, by means of a camel's hair probang, to the affected parts, every two or three hours, and in eighteen cases on which he has used it the effect has been all he could wish.

Treatment of Eclampsia by Bleeding and Chloral.

M. Guyot related to the Société Médicale des Hôpitaux, that a child, aged eleven and a half years, was seized with an attack of eclampsia on the twenty-second day of an attack of scarlatina complicated with albuminuria. He was in a state of coma, and near death, when M. Guyot bled him to the extent of 300 grams, and gave him two enemata of chloral. The child recovered rapidly.

Correspondence.

A Case of Poisoning by Opium, Successfully Treated with Atropia—without Emesis.

Ed. Med. and Surg. Reporter:—

The following case has some features of special interest:—

A. B., aged fifty, coach painter, has been a patient of mine for the last three years, during which time he has had several attacks of delirium tremens, which yielded rapidly to the usual treatment. On the evening of June 2d, 1881, at nine o'clock, I was called to see him—word being left at my residence that he was very ill—not able to speak, etc., but gave no clue to the existing trouble. I soon started for his house, about two miles distant, and on arriving there, was told that he had taken one ounce of laudanum (such as is usually kept at country stores), about one hour before I arrived. I found the pupil contracted to the size of the smallest pin-head, the patient senseless and incapable of being aroused, the breathing slow and somewhat stertorous. Pulse rather slow, but of good volume. The family being intelligent people, and having had the same trouble to a small extent some years ago, had freely used all the domestic emetics without any effect, and I found, after forcing the mouth open, in order to administer a huge dose of ipecacuanha and zinc. sulph., that emesis could not be produced, on account of the torpid condition of the brain. I was now in a dilemma, and no stomach pump at hand. I drove rapidly back to my house, for my hypodermic syringe, and on my return with it I gave an injection of $\frac{3}{32}$ of a grain of sulphate of atropia. This was nearly two hours after the laudanum had been taken. In four minutes after the atropia was administered there was a decided amelioration of all the symptoms. This improvement lasted for fifteen minutes, when the stupor increased to some extent. After waiting five minutes longer, I repeated the injection, using the same quantity. Rapid and permanent improvement quickly followed; of course, the usual means of flagellation with wet towel, walking the patient, shouting, etc., to keep him awake, were not neglected; also strong coffee, etc. Before leaving the patient, at midnight, I gave by the mouth forty-five drops of tincture of belladonna (made from Squire's extract), and ordered thirty drops of same to be given at 3 A.M., and same quantity at 6 A.M., if required. The improvement, however, was so marked that the dose at 6 A.M. was not given. I saw the patient the next day (June 11) at 10 A.M., found him quite convalescent, and needing only some fluid extract of valerian and Hoffman's anodyne, to straighten up his nervous system after his debauch. I dismissed the case on June 12th, as cured.

This case, I think, fully proves the power of atropia as an antidote to opium—as the cure was effected, not by getting rid of the poison, but by neutralizing it in the system, and that, too, when emesis could not be produced, and when the symptoms indicated a speedy death—consequently, I shall "tie to it" with absolute confidence, in future. It will be noticed that my doses were large, which is additional proof of the antagonism of the two drugs, otherwise serious consequences would have followed their administration.

Jenkintown, Pa. Robert Coltman, M.D.

Rœtheln.

Ed. Med. and Surg. Reporter:—

In the Reporter of May 28th, 1881, Dr. Hubbard, of Wauconda, Ill., reported a case of "Obscure Rubeola," and asked if it could be considered a case of rœtheln. I think it was most certainly a case of roseola. In our village, of 1200 inhabitants, we have had an epidemic of roseola during the past spring; one-half of the population, adults as well as children, have been visited with it. The diagnosis is rendered easy if attention be paid to the following points of difference between it and rubeola and scarlatina. The rash of roseola is *pink*, and on looking at it *sidewise* it seems as if the skin had been tattooed with pink ink; there is no elevation of the skin, as in rubeola. The eruption is larger and paler than the rash of scarlatina, and not so dark as in rubeola. There is not the same amount of coryza as is seen with rubeola; and not so severe (if any) throat symptoms as are usually present in scarlatina. There is also very little febrile movement, and the duration of roseola is only for a few days; few of the patients take to the bed during the course of this disease. Some who have had rubeola severely a few months previous have just had an attack of roseola; and the same is true of scarlatina.

John C. Holmes, M.D.

Cranbury, N. J., June 13th, 1881.

News and Miscellany.

The Pennsylvania Medical Law.

We give below a correct copy of the Medical Registration Act as approved by the Governor of this State, June 8th, 1881. We commend it to the careful attention of the physicians of this commonwealth. It should be added in this connection that the passage of this act is largely owing to the self sacrificing and disinterested endeavors of Dr. R. L. Sibbet, of Carlisle, Chairman of the Committee on Medical Legislation:—

An Act to Provide for the Registration of all Practitioners of Medicine and Surgery.

Section 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it it is hereby enacted by the authority of the same:—

That the Prothonotary of each county shall purchase a book of suitable size, to be known as the Medical Register of the County (if such book has not been purchased already), and shall set apart one full page for the registration of each practitioner; and when any practitioner shall depart this life, or remove from the county, he shall make a note of the same at the bottom of the page, and shall perform such other duties as are required by this act.

Sec. 2. Every person who shall practice medicine or surgery, or any of the branches of

medicine or surgery, for gain, or shall receive or accept for his or her services as a practitioner of medicine or surgery any fee or reward, directly or indirectly, shall be a graduate of a legally chartered medical college or university having authority to confer the degree of doctor of medicine (except as provided for in section five of this act); and such persons shall present to the Prothonotary of the county in which he or she resides or sojourns, his or her medical diploma, as well as a true copy of the same, including any endorsements thereon, and shall make affidavit before him that the diploma and endorsements are genuine thereupon; the Prothonotary shall enter the following in the register, to wit: The name, in full, of the practitioner, his or her place of nativity, his or her place of residence, the name of the college or university that has conferred the degree of Doctor of Medicine, the year when such degree was conferred, and in like manner any other degree or degrees that the practitioner may desire to place on record; to all of which the practitioner shall likewise make affidavit before the Prothonotary, and the Prothonotary shall place the copy of such diploma, including the endorsements, on file in his office, for inspection by the public.

Sec. 3. Any person whose medical diploma has been destroyed or lost, shall present to the Prothonotary of the county in which he or she resides or sojourns, a duly certified copy of his or her diploma; but if the same is not obtainable, a statement of this fact, together with the names of the professors whose lectures he or she attended, and the branches of study upon which each professor lectured, to all of which the practitioner shall make affidavit before the Prothonotary, after which the practitioner shall be allowed to register in manner and form as indicated in section two of this act, and the Prothonotary shall place such certified statement on file in his office, for inspection by the public.

Sec. 4. Any person who may desire to commence the practice of medicine or surgery in this State after the passage of this act, having a medical diploma issued or purporting to have been issued by any college, university, society or association in another State or foreign country, shall lay the same before the faculty of one of the medical colleges or universities of this Commonwealth for inspection; and the faculty, being satisfied as to the qualifications of the applicant and the genuineness of the diploma, shall direct the dean of the faculty to endorse the same, after which such person shall be allowed to register as required by section two of this act.

Sec. 5. Any person who has been in the continuous practice of medicine or surgery in this Commonwealth since one thousand eight hundred and seventy-one, without the degree of doctor of medicine, shall be allowed to continue such practice; but such person shall nevertheless appear before the Prothonotary of the county in which he or she resides, and shall present to him a written statement of these facts, to which the practitioner shall make affidavit. Thereupon the Prothonotary shall enter the following in the register, to wit: The name in full of the practitioner, his or her place of nativity, his or her place of residence, the time of continuous practice in this Commonwealth, and the place or places where such practice was pursued, to all of which the practitioner shall likewise make affidavit, and the Prothonotary shall place the certified statement on file in his office, for inspection by the public.

Sec. 6. Every practitioner who shall be admitted to registration shall pay to the Prothonotary one dollar, which shall be compensation in full for registration, and the Prothonotary shall give a receipt for the same.

Sec. 7. Any practitioner who shall present to the faculty of an institution, for endorsement, or to a Prothonotary, a diploma which has been obtained fraudulently, or is in whole or part a forgery, or shall make affidavit to any false statement to be filed or registered, or shall practice medicine or surgery without conforming to the requirements of this act, or shall otherwise violate or neglect to comply with any of the provisions of this act, shall be deemed guilty of a misdemeanor, and, on conviction, shall be punished for each and every offence by a fine of one hundred dollars, one-half to be paid to the prosecutor and the other half to be paid to the county, or be imprisoned in the county jail of the proper county for a term not exceeding one year, or both, or either, at the discretion of the court.

Sec. 8. Nothing in this act shall be so construed as to prevent any physician or surgeon legally qualified to practice medicine or surgery in the State in which he or she resides from practicing in this Commonwealth: but any person or persons opening an office, or appointing any place where he or she may meet patients or receive calls, shall be deemed a sojourner, and shall conform to the requirements of this act.

Sec. 9. This act shall take effect on the first day of June, one thousand eight hundred and eighty-one.

Sec. 10. That all acts or parts of acts heretofore passed, and inconsistent with this act, be and the same are hereby repealed.

Items.

—*Puck* says the order of the Knights of the Goitre are principally found in Switzerland. Its members are all swells.

—Five hundred children have been taken from the public schools at Atlanta, Ga., on account of the presence of a mysterious disease.

—The Japanese Government has appointed a Special Commissioner, Mr. Monosuke Sano, to study the subject of cremation, and he is now investigating the merits of the Italian system, at Milan.

—A lawless gang in West Virginia, calling themselves "Red Men," recently took Dr. Daniel Cain, of West county, from his house at midnight and gave him a severe flogging, for refusing to use steam in his flouring mill.

—The State Board of Health of West Virginia has been duly commissioned by the Governor. Dr. J. E. Reeves has been appointed for six years. Dr. Reeves is now President of the State Medical Society, and it is mainly to his endeavors that the Board of Health owes its existence.

OBITUARY NOTICES.

PROF. SKODA.

The cable, on June 14th, announced the death of Dr. Josef Skoda, the distinguished professor at Vienna. He was born in Bohemia, in 1805, graduated at the Vienna medical schools in 1831, in 1834 became second physician to the general hospital at Vienna, and became successively Physician for the Division of Lung Diseases, Chief Physician of the Hospital, Professor of Clinics, and a member of the Vienna Academy of Sciences. Professor Skoda was one of the first to popularize the use of the stethoscope, was a great authority on pathological anatomy and on the various methods of auscultation and percussion, and was considered the head of the new German school of diagnosis.

QUERIES AND REPLIES.

Chronic Colitis

MR. EDITOR.—I would suggest, in answer to "Query" on chronic colitis, June 11th, liq. ferri pernitratis, gtt. x, in wineglass of sweetened water, four times a day, continued two weeks or more, as may best seem fit. S. L. WEST, M.D.

Wilmington, Del.

MR. EDITOR.--In reply to Wm. H. C., of Ill., I would suggest a plan of treatment which has for years been effectual in my hands. Give your patient ℥xxx of tinct. opii, in water; this will arrest the peristaltic action of the stomach, and renders it tolerant of the following dose in half an hour :—

Pulv. ipecacuanha, grs. xl, in some syrup or honey. No fluid to be given for at least three hours. If very thirsty, ice can be sucked.

This remedy seldom produces nausea or vomiting, in large doses, if the above plan is carried out The ipecac. has a beneficial action upon the skin, by causing an increased secretion of mucus, and by restoring the deranged capillary circulation of the liver and intestines to its normal state. After this I give teaspoonful doses of ext. belæ liquid, three times a day. One dose is generally enough of the ipecac.; if not, give another in about eight hours from the first.

While a surgeon in H. M.'s Army in the East Indies, where chronic colitis or dysentery is so common, the above treatment seldom failed. The hygienic condition d urrounding of the patient must be attended to. This disease is malarial, having an affinity for the glandular tructure of the intestines. And last, but not least, send your patient for a change of air, if possible, to the sea shore.

H. ISAAC JONES, L.R.C.P.E., L.F.P.& S G.

Scranton, Pa. Mem. Am. Med. Association.

MR. EDITOR.—In answer to Wm. H. C., Ill., in your last issue, I would say, I had, in 1874, a similar case, differing only in severity; my patient had twelve to fifteen stools daily; after all else had failed he fell into my hands; I put him on—

℞.	Pulv. ipecac.,	3ss	
	Ext. opii,	gr. j.	M.
	Ft. pil., No. vj, div.		

To be taken at once, with directions to keep perfectly quiet in recumbent position. On following day stools had lessened to one third; the same dose repeated and the following twenty-four hours were passed without any movement of the bowels, when a course of tonic treatment, with careful diet, completed the cure; he has never had any symptom of the trouble since. Not wishing to take up too much of your valuable space, I refrain from dilating upon it. I reported the case to our County Medical Society, at the time. Should the gentleman incline to try this remedy, I would be much pleased to hear of the result. D. SCHLEMER, M.D.

Elizabeth, N. J.

Dr. J. M., of Indiana, writes: What is Reid's method of reducing dislocation?"

Ans.—We presume you refer to the method introduced by Dr. W. W. Reid, of Rochester, N. Y., in 1851. It is by manipulation, and may be found described in "Hamilton on Fractures and Dislocations," page 752, and elsewhere.

Dr. Lex, of Ohio.—We shall take an early opportunity to discuss the subject of the relationship of medical societies, and make some suggestions thereon.

MARRIAGES.

BLACKLY—SHERRARD.—At the Parsonage, Prosperity, Pa., May 18th, by Rev. J. H. Sherrard, assisted by Rev. T J. Sherrard, Oliver L. Blackly, M.D., of Sparta, and Miss Anna R., daughter of the officiating minister.

CAMPBELL—KREMER.—On May 25th, by Rev. W. H. Logan, G. W. Campbell, M.D., of Newport, and Sallie A., youngest daughter of Perry Kremer, Esq., of Millerstown, Perry county, Pa.

CRANE—ECKARD.—June 3d, at Abington, Pa., by Rev. J. R. Eckard, Charles L. Crane, M.D., of Sumter county, S. C., and Anna Maria, daughter of the officiating clergyman.

DISBROW—CALHOUN.—On Thursday, April 21st, at the residence of the bride's parents, No. 713 Lexington Ave., by the Rev. Stephen H. Tyng, Jr., D.D., Clara Louise Calhoun and Robert N. Disbrow, M.D., both of New York.

GREENE—MENAGER.—By his Honor, Wm. R. Grace, Mayor of New York city, Dr. Wm. R. Greene, of Philadelphia, and Miss Sarah Menager, of Paris, France.

HARRIS—LEGGETT.—By Rev. S. S. Gilson, May 10th, 1881, at the Presbyterian Parsonage in Dennison, O., Dr. George M. Harris, of Lorraine, O., and Miss Dorret M. Leggett, of Uhricksville, O.

SPALDING—GARRETT.—At St. Canicus' Church, Mahanoy City, Pa., on Wednesday, June 1st, 1881, by the Rev. M. A. Ryan, Dr. S. C. Spalding, of Shenandoah, and Miss Agnes Garrett, of Mahanoy City.

DEATHS.

COCKEY.—At Rye, Saturday, May 21st, John H. T. Cockey, M.D.

COOPER.—On the 27th of May, in Colfax county, New Mexico, Dr. Lehman Adams Cooper, of erysipelas, in the forty-second year of his age.

GREGG.—Entered into rest, on the evening of the 31st ult., H. Albina Gregg, aged sixty-five years.

HALSTED.—At his father's residence, Sing Sing, N. Y., on Tuesday, May 24th, Richard Frederick Halsted, M.D., eldest son of James W. and Mary A. Halsted.

JONES.—Friday, May 20th, at 4 P.M., at his late residence, No. 43 West 56th street, New York, Alanson S. Jones, M.D.

LANGSTROTH.—On May 8th, 1881, at Vinton, Iowa, Edward F. B. Langstroth, M.D.

ROY.—On Friday evening, May 20th, at his late residence, No. 216 West 31th street, New York, Dr. Enos G. Roy, in the fifty first year of his age.

SABINE.—In London, Ontario, on the 1st instant, Dr. Joseph B. Sabine, aged fifty-six years.

VAN WAGNER.—At Madison, N. J., May 30th, Frederick J. Van Wagner, M.D., in the forty-third year of his age.
